HEADQUARTERS FOR

Early Italian & Cyprian Queens.

Imported and home-bred; nuclei and full colonies. For quality and purity, my stock of bees can not be excelled in the United States. I make a specialty of manufacturing the Dunham foundation. Try it. If you wish to purchase Bees or Supplies, send for my new Circular containing directions for introducing queens, remarks on the new races of Bees, etc.

Address
11td Dr. J. P. H. BROWN, Augusta, Ga.

Cash for Beeswax!

Will pay 26c per lb. cash, or 28c in trade for any quantity of good, fair, average beeswax, delivered at our R. R. station. The same will be sold to those who wish to purchase, at 32c per lb., or 36c for best selected wax.

Unless you put your name on the box, and tell how much you have sent, I can not hold myself responsible for mistakes. It will not pay as a general thing to send wax by express.

A. I. ROOT, Medina, Ohio.

BARNES' FOOT-POWER MACHINERY.

Read what J. I. PARKER, of CHARLTON, N. Y., says:—“We got with one of your Combined Machines last winter 50 chaff hives with 7 in. cap, 100 honey racks, 200 bread frames, 2,000 honey boxes and a great deal of other work. This winter we have double the amount of bee hives, etc., to make and we expect to do it all with this Saw. It will do all you say it will. Catalogue and Price List Free. Address—W. F. & JOHN BARNES, No. 68 Ruby street, Rockford, Ill.

When more convenient, orders for Barnes' Foot-Power Machinery may be sent to me. A. I. ROOT.

Obituary.

We are pained to notice the death of our old friend F. N. Wilder, of Forsyth, Ga. He was one of the old friends of GLEANINGS, and has been an enthusiastic and successful bee-keeper, widely known in his vicinity. His last letter, if I am correct, is found on page 402, June number. He was about 36 years of age, and an earnest and consistent member of the Methodist Church since his 19th year. It is said of him that he has never, during his whole married life, failed to have family prayers.

Great peace have they which love thy law, and nothing shall offend them.—Ps. 119: 165.

KIND WORDS FROM OUR CUSTOMERS.

OUR FDN. AND FDN. MILLS.

Your 10-inch foundation machine received in good order. We have tried it, and the bees have tried the foundation. All parties are well satisfied.
Columbus, Wis., June 6, 1884. SMITH & MORGAN.

THE WIRE-IMBEDDER FOR PUTTING FDN. INTO WIRED FRAMES.

Just in time, the nice wire-imbedder came to hand to-day. I am well pleased in the prompt way you have of doing business. W. RIGGEN.
North Salem, Ind., June 7, 1884.

SOME KIND WORDS FROM MY OWN PASTOR.

I thank you for your Christian and sensible article in the Nov. "Homes." May God grant that it may become more and more the habit of Christians to take their religion into their conflicts with troublesome boys or men rather than their firearms.

Medina, O., Nov. 21, 1884.

C. J. RYDER.

OUR EXTRACTORS IN ARKANSAS.

The extractor was a "dandy" and a show in the county—the only one in the county. The people crowded in, to see the honey taken out without injuring the combs, till the house was full in every room. If I had charged an admission fee I could have gotten my money back. WM. DRAKE.
Colt Station, Ark.

SOME KIND WORDS FROM AN A B C SCHOLAR.

Well, we are closing up another year. I began dealing with you last spring in a small way, but my apiary is growing, and so are my ideas. If my prosperity keeps up I shall soon be a customer worth looking after. I began in the spring of 1884 with one small colony of beautiful Italians. My apiary has grown to 11 at this writing, and I have purchased only one, a full Italian swarm, for which I gave \$4.00. I have 9 of my colonies in chaff hives, which I made myself, after the instructions given in the A B C book, on a buzz-saw I constructed myself. But after making those 9 hives I recognized the truth of your statement, that it takes a superabun-

dance of muscle and enthusiasm to run one of them; or, as an old fellow put it who was looking at me while at work, "It takes a heap o' trompin'." Allow me to say, that my success is due to the accuracy of your directions in your book. I suppose there was not a day during the whole summer that I did not pay the closest attention to them. My neighbor constantly prophesied I would kill my bees, and I could get him to open his hives only after the utmost urging. Result, I have grown from one to 11; he has grown from 7 to 9, and I have had to keep constant watch to keep my bees from robbing his. My honey crop was short, because of the excessive drought. And now, allow me to thank you for the prompt and honest attention you have given my orders, and to hope that I shall be able to deal with you for long years to come. Honestly and sincerely your friend,
C. M. ROBERTS.

Chillicothe, O., Dec. 11, 1884.

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or \$2.00 per year.

\$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or \$2.00 per year.

Those whose names appear below agree to furnish Italian queens for \$1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen is reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for \$1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

HONEY COLUMN.

CITY MARKETS.

NEW YORK.—*Honey*.—We beg to inform you that our market is well stocked with comb honey, with an unsatisfactory demand for same, even at the following low prices:

Fancy white clover, in 1-lb. sections, per lb.,	16@18c
" " " 2-lb. "	14@16
Fair to good white, in 1 & 2 lb. "	13@15
Fancy buckwheat, in 1-lb. "	10@11
" " " 2-lb. "	9@9½
Ordinary grades, in 1 & 2 lb. "	No demand.
Extracted, white clover, in kegs or small bbls.,	8@8½
" " " buckwheat, " " "	6@7
Beeswax, prime yellow, per lb.,	31@32

McCAUL & HILDRETH,
31 Hudson Street, cor. Duane St.,
New York City.

Dec. 19, 1884.

CINCINNATI.—*Honey*.—There is nothing very encouraging in the market. Supply is good of comb and extracted honey; and while the retail demand is fair for the latter, it is slow for comb honey. Demand for extracted honey from manufacturers, is very dull. Prices range low, caused not so much by large supplies as by the low price of sugar, adulterations, and stagnation in the manufacturing business. Choice comb honey in 1 and 2 lb. sections brings 15@16c per lb. on arrival, and extracted honey, 6@9c. *Beeswax*.—Arrivals are slow, with a good home demand. Good yellow brings 28@29c on arrival.

CHAS. F. MUTH,

S. E. Cor. Freeman and Central Avenues,

Dec. 24, 1884.

Cincinnati, O.

ST. LOUIS.—*Honey*.—There has been no change in extracted honey since our last report; only retail demand. Southern in barrels, worth from 5½ @ 6c.; in kegs, 7c. for choice; in cans, 10c., at retail. Very little demand for comb honey. White clover in one-pound sections, 17 to 18c.; in two-pound sections, 15 to 16c. per pound. Dark honey not wanted.

Beeswax.—Not much arriving; worth from 27 @ 28c.

W. T. ANDERSON & Co.,

Dec. 24, 1884.

104 N. Third Street, St. Louis, Mo.

MILWAUKEE.—*Honey*.—The honey market here is rather dull for this season of the year, and the supply fair, and quality of stock generally fine and in good order. Quote, White 1-lb. sections, 13 @ 14c.; white 2-lb. sections, 12 @ 13c.; extracted, in kegs, 8c., with package; in cans, 9c. *Beeswax*.—28 @ 30c. pure.

A. V. BISHOP,

Dec. 24, 1884.

142 West Water St., Milwaukee, Wis.

CLEVELAND.—*Honey*.—The honey market is very much neglected, scarcely any wanted. Prices are unchanged; best white 1-lb. sections selling at 15@16, second quality 13@14. Best white, in 1½ and 2 lb. sections, 14 cts. Extracted not salable.

Beeswax.—28 cts.

A. C. KENDEL,

Dec. 27, 1884.

115 Ontario St., Cleveland, Ohio.

KANSAS CITY.—*Honey*.—Market very quiet; little honey moving; prices lower—about 1 cent on 1-lb. sections 2@3 cents on 2-lb. sections. Extracted dull, 2@3 cents lower, with very little doing.

Dec. 22, 1884.

CLEMONS, CLOON & Co.,

Cor 4th and Walnut Streets, K. C., Mo.

DETROIT.—*Honey*.—The honey market is rather dull and well supplied. Good comb is quoted at 12@14 cents.

A. B. WEED,

Dec. 23, 1884.

Detroit, Mich.,

BOSTON.—*Honey*.—Our demand for honey is very light, and prices are off from 16@2 cts. per pound.

Dec. 23, 1884.

BLAKE & RIPLEY,

57 Chatham St., Boston, Mass.

300 Colonies of Bees for Sale,

Also 40 acres of land adjoining the city; good house, and plenty of good water.

ANTHONY OPP,

HEADQUARTERS

IN THE

SOUTH

FOR THE MANUFACTURE AND SALE OF

BEE-KEEPERS' SUPPLIES

The Only Steam Factory Erected in the South.

Exclusively for the Manufacture of Hives,

Frames, Sections, &c., &c.

Viallon, and Root Simplicity Hives, and Sections a specialty. the 4x4½ all-in-one-piece

Comb Foundation made on the Root and Dunham mill, of pure wax, and worked on shares.

Extractors, Smokers, Honey - Knives, Bee- Veils, and every thing needed in the apiary.

Italian Queens and Bees. No other races in my apiary or in the neighborhood. The superiority of the queens reared in my apiary is so well established, that no commendation is required. I send out no queen that I would not have for myself; and any one receiving a defective or worthless queen from me will have it replaced. Proposals from Dealers to mail a given number weekly, solicited.

Untested Queens in April, \$1.25; in May, \$1.15; in June and after, \$1.00. Rates per dozen given on application.

TESTED QUEENS from March 1st to July 1st, \$2.50; and after, \$2.00.

SELECTED TESTED QUEENS, Reared previous season, to breed from, \$3.00. All my queens are reared from selected imported mothers of my own importation, and from selected daughters.

Early 4-Frame Nucleus, With tested queen, \$5.00. I have made a specialty of the 4-frame nucleus for the last seven years, and have sent them out to all parts of the United States and Canada without loss.

Every Nucleus I send out contains at least three pounds of bees when received and sent out in the full-size Langstroth frame. They are cheaper and more advantageous than bees by the pound. Any one wishing a list of those to whom I sent nuclei the last season can have it on application, so they can inquire what they were, etc.

Full Colonies In any quantity. Perfect satisfaction guaranteed in every instance. For more particulars, and prices, send for my Descriptive Illustrated Catalogue. Cash market price for wax.

Clubs to different post-offices, NOT LESS than 30 cts. each. Sent postpaid in the U. S. and Canada. To all other countries of the Universal Postal Union, the price is extra. To all countries NOT of the U. P. U., 42 cts. per year extra.

NOTES FROM THE BANNER APIARY.
NO. 61.
FOUNDATION IN THE BROOD-NEST.

FRIEND ROOT:—You will remember that we discussed this question at the Lansing convention; but as many of your readers were not there, I will, with your permission, reply to your criticisms upon my article on page 801, Dec. GLEANINGS. You say, colonies with sheets of fdn., and with empty frames, have been tried side by side for years, and in thousands of apiaries, and the result was in favor of the fdn. You also speak of the excellent results obtained by hiving swarms upon empty combs, and extracting the honey. All this I admit; but, to my mind, these illustrations are not to the point. If a swarm is compelled to build *all* of its combs, both *store* and brood, there is no question in my mind but that it would be outstripped by a swarm furnished with fdn. or combs, but how will it be when the *surplus* department is furnished with fdn. or combs, and the bees allowed to build natural combs in the brood-nest? Have you, friend R., tried such an experiment, or do you know of any one who has? and if so, with what result? Prof. Cook offered an explanation of why I apparently secured more honey when no fdn. was used in the brood-nest, and the explanation is reasonable. He said the honey was stored in the sections to a greater extent, instead of in the brood-nest, when no fdn. was used in the brood-nest; and, as I did not compare the weight of the brood-nests in the fall, it is possible that the professor's explanation is the true one. This is the one weak point in my experiment. Another season I will try to make

my experiments more conclusive. Prof. Cook says bees do not secrete wax unless they have use for it; but, is it not possible that a newly hived swarm, during a good flow of honey, can secrete enough wax to fill their brood-nest, if given fdn. in the surplus department, more cheaply than we can buy fdn. for them? The best way that I know of to decide this question is by such experiments as I made last season; and if it is decided that more surplus is secured simply because less honey is deposited in the brood-nest, it should not be forgotten that this space in the brood-nest that *would have been* occupied with honey, had fdn. been used, has been occupied with *brood*, and that fall will find the hive full of bees instead of honey; the honey can be sold for a good price, and the combs filled with sugar syrup.

You say, "It seems to me, that instead of deciding we do not need fdn. or empty combs, we ought to decide that the method of management was not quite the thing." I do not think this a fair decision, and I think you will agree with me when I tell you that no other bee-keeper in this county, so far as I have learned, has received so large a yield *pro rata* as myself, while the commission men pronounced it the finest honey they have handled this season. One bee-keeper, living 2½ miles from here, began the season with about 36 colonies, and increased to about 76, but received only about 10 lbs. per colony of surplus. At the convention at Chicago, *only one* reported a better yield of comb honey than myself. In the face of this, do you think it would be fair to say, "The method of management was not quite the thing"? *Per contra*, in the fall I fed my bees 10 lbs. of sugar per colony, on an average, to prepare them for winter; but as the honey "squeezed"

from the brood-nest into the sections netted me, upon an average, 15 cts. per pound; the sugar needed to take its place in the brood-combs cost only 7 cts. per lb., and is a safer winter food than honey, do you think it fair, my friend, to say "the method of management was not quite the thing"?

This question of fdn. or no fdn. in the brood-nest is an important one, and I hope that a large number of experiments will be made another season. Let all remember, however, that when fdn. or combs are placed in the surplus department, and the brood-frames left empty, a queen-excluding honey-board is needed.

THE HEDDON FEEDER.

As I have used the Heddon feeders (30 of them) two years, and fed about 4000 lbs. of feed, part of it being honey and part sugar syrup, perhaps I may be allowed to answer your objections to it. They are such shape that they pile away quite snugly, 16 of them making a pile only 6 feet high; but, as they are painted, they can be piled up, out of doors, if there is no room inside. The cover is simply a board (the hive-cover) cleated at each end, so that it can not warp. I have never had a particle of trouble in this direction, and no weights are used to hold the cover down. The feed used is not thin, like water, and the pressure is not great enough to cause it to "spout" through the saw-cuts; it comes through them, and then down the side of the partition; at least, this is the way I should explain the matter, as I have never shoved the cover back far enough to see exactly in what shape the feed comes through; but I do know that I have never seen any daubed bees, or those that gave evidence of having been daubed, and I have never boiled the sugar syrup as mentioned by Mr. Heddon, simply having dissolved it with hot water, and it crystallizes quite badly until the bees get it into their cells. I do not think there are half a dozen dead bees in any one feeder, and they have been in use two years. To prevent the feeder from leaking it is only necessary to paint with white lead the edges of the pieces before putting them together. This feeder, and the grooved board to be used with a fruit-jar, are the only ones I ever thought well enough of to even try.

W. Z. HUTCHINSON, 68-94.

Rogersville, Genesee Co., Mich.

With the explanation given by yourself, and that of friend Cook at the convention, I have no doubt you are right in regard to the matter, friend H.; and in your remarks above you suggest one thing that I have often mentioned before, but I had not thought of it in connection with this matter; viz., that a new swarm of bees seem to do better where they have some comb to build than where they have all finished combs already furnished. I once urged this as a reason why we should not fill our section boxes completely. But your idea is a new one, of filling the section boxes completely, and letting the bees indulge their propensity for comb-building, and use the wax that exudes out of their bodies, in the brood-frames below. In the extract you make, however, from what I said last month, I now for the first time discover that the word *decide*, in the last part of the sentence, is not the one I meant to use. I simply meant to suggest that we could not decide any thing at present, and that before deciding, we should investigate your method of management, and see if it were just the

thing. Most of the friends who know me well, are aware that I often use a word that does not express exactly the meaning I intended, for the simple reason that the word I want does not just then occur to me. I had no thought of conveying the idea as you put it.—I am very glad to know you succeeded in making feed without boiling, because boiling does seem to me an unnecessary nuisance; not only a nuisance to yourself, but to your wife and family, unless a special stove be provided; and this special stove, in the hands of the average bee-keeper, is generally a pretty big nuisance. I am also glad to have so good a report from the feeder: for not having used it myself, I was not prepared to decide. You probably purchased your feeders and covers of friend Heddon, and I hope you will excuse me for still suggesting that the feeders and covers both be purchased of friend H., or of some supply-dealer who makes his work carefully, or there will be great trouble from leaking and warping covers.

THE MICHIGAN STATE CONVENTION.

WHAT I SAW AND LEARNED.

I STARTED one day earlier, in order to visit the State fish-hatchery at Sandusky. In order to make connections I had to ride on a freight train two or three hours. Three or four other individuals shared the rather dismal freight car during this long ride, and the slow monotony of the trip was improved by getting acquainted with each other. Some seemed disposed to talk, and talked quite freely, and others did not. I, for want of something better to do, fell to studying humanity. I had but little time to stop at Sandusky, I knew, and I was very anxious to find out where the State fishery was located, and therefore I asked every new comer as he came into the car if he was acquainted in Sandusky; and if so, did he know any thing about the fish-hatchery. Nobody knew any thing about it, nor had I ever heard of such a thing. One individual volunteered the remark, that he did not know much about German carp, but he did know something about feeding fish. He used to be connected with an eating-house on the dock by the lake; and the cook, in order to get rid of his slops, just hoisted it out of the window. Well, in due time a lot of voracious cat-fish learned to hang around the said window, for the choice morsels that came to them every time the table was cleared. These fish got so tame they would come clear up and hang around like a lot of pigs or chickens, for their daily meal. Pretty soon the cook took the hint and threw out a baited hook, and not only supplied the table with cat-fish, but presented his friends right and left with great whooppers for bakes. The narrator had one such, and the family voted it so delicious that he applied for another. This time they got a larger one still. But, oh dear me! in preparing him for the oven a great horrid dead wharf rat was found inside of the big fish. None of the family ever wanted any more of the cat-fish, and my friend said it sickened him for all

time to come of every thing belonging to the fish tribe. Is it not funny, what prejudice will do?

By this time a very genteel-looking man came in, and somehow his appearance seemed to rather forbid conversation. I finally decided, however, that I would see whether it were true that we can tell very much about a man by his looks. He admitted that he lived in Sandusky, and was pretty well acquainted, but answered so briefly that I was almost discouraged on the carp question. However, we neared the place, and necessity made me bold. Oh, yes! he knew all about the State fishery; had seen the little chaps wiggle about in the glass jars. It was down by the waterworks. He would show me the place; and after studying up the time of trains, decided for me that by close figuring I could get about twenty minutes for my visit at the fishery. I began to repent a little of my former uncharitable conjecture in regard to him; and when the train slacked up near the station, and he suggested we had better jump off and run, trusting to the chances of a street-car, I became a good deal ashamed of myself. A car had just left, and I slacked up my running, deciding that it was too nearly out of sight to leave any chance for catching it. He, however, with a shrill whistle, brought them up, even away off in the distance, got me into the car, pointed out the fine buildings of the city, told me of a short cut to take in going back, pointed out the hatchery, then nodded as he left me, without seeming to think he had done me any service at all; and yet without his kind assistance I should have entirely failed in my project, and a day's work would have been lost. I did thank him as well as I knew how, and I mentally resolved to try never again to be guilty of forming uncharitable impressions of people of whom I know nothing, for so silly a reason as that they look a little bit proud and aristocratic, under my countrified gaze. I feel ashamed of myself every time I think of it. What a foolish thing it is to think ill of a person you don't know! And, come to think of it, I do not know but it is ten times more foolish to be tempted to think ill of people around you whom you *do* know. May God have mercy upon me a sinner, and I fear a sad sinner right in this line.

The fish-building stood right on the shore of the lake, or bay, rather; in fact, it is partly over the water. Long vats inside remind one somewhat of a cheese-factory. In the center of the building were long rows of glass jars, perhaps several hundred of them. Each jar held, may be, three gallons. The jars are called the Chase automatic jar. Water drawn from away out in the lake, through the medium of the waterworks, comes into the building near the ceiling. It pours into the jars through a tube that goes to the bottom of the jar. Of course, this makes the water boil over. A lip to the jar then pours it into a tube that goes into the next jar, and so a gurgling stream of water goes through the jars constantly, day and night, for many months, and from there out into the lake. Well, these jars are filled with eggs of white fish in countless millions.

These eggs look like white pearls, about the size of common shot. Patiently the operatives watch and wait nature's time, for three or four long months. Then the eggs, even in this cold lake water, hatch out little fish, and the fish wiggle out up through the jars, and so out with the current into the lake, and Lake Erie is peopled with white fishes. Is it not wonderful?

They do not hatch carp in that way. Carp are hatched in ponds, as described in the different articles that have appeared. But along the vats, along the outside of the building, little carp of all sizes were swimming. The gentlemanly superintendent, Mr. Henry Douglas, scooped up a lot of them with a little net attached to a frame that just filled the vat. By pushing this down the center of the vat, and moving it toward the end, all the fish that could not go through the meshes of the net were pulled up at one haul. The fish did not seem to be troubled or alarmed about it. I picked up a mirror carp about the size of my hand, and he lay still while I admired him, as if it were the most natural thing in the world. How I did wish that Huber were there! He has lately learned to express his admiration or thanks by saying "nice." But he can not say the whole word, and so he just says "ni." When I feed him at the table, and give him something, he looks up with an appreciative twinkle in his blue eyes, and ejaculates "ni." So it is with an apple, or any thing else to admire. One day he put out his little fat leg, and giving it a pat with his soft hand said to me inquiringly, "Papa, ni?" Well, I presume the juveniles who will likely read this would have almost screamed with delight to have seen these little fishes.

By the way, as soon as I have begun to study carp, the whole finny tribes have become wonderfully beautiful and fascinating in my eyes. How can one ever appreciate the nice ("ni") things in this world unless he has looked into it and studied it and become intimately acquainted with it? During the past year I have learned to love most intensely quite a number of things that I never loved before. For instance, I love strawberry-plants, and I tell you I really feel a thrill of happiness every time I pass a garden with a pretty plat of thrifty, nicely cared-for strawberries. Well, when I cross a bridge a little beyond this garden, and catch a glimpse of the finny tribes gliding about over the gravelly bed, I feel another thrill of happiness. When I went over to the college farm with our good friend Prof. Cook, with a number of other bee-friends, to stay over night, there were several things that made me happy. One was a great cluster of poinsettia in the greenhouse, almost dripping with honey. We licked it out of the cup-shaped blossoms, and when we came around again there was another supply almost ready to be "licked" again. Friend Cook's young hopeful, "Bertie," was just getting crazy on poultry when I was there; and as that used to be my boyhood hobby, Bertie and I soon had many ideas in common. While they were hitching up to go back to the convention, Bertie and I and his little sister had a chase out around the barns

to find his golden game bantams. Well, they had wandered away, and we could not find them; but Bertie found a fresh-laid egg, a diminutive hen's-egg, of a faint orange tint, clean and spotless, and beautiful in proportion. I wanted the egg to show to Huber, more than I dared to tell; and the sight of that egg gave me another thrill of pleasure, and ever since that day I have felt an unaccountable love for poultry. I went and got my old poultry book, "An Egg Farm," and somehow every page seemed to give me a new thrill of delight, bringing back my boyhood days, and making me feel glad that I had now a very pretty lot of young pullets that might be laying if they only had better quarters. Well, I am feeling unusually happy this bright wintry morning; and one thing that I feel happy about is, that it is a beautiful sunshiny day; and after I get the printers supplied with copy, and my morning mail read, I am going to scrape acquaintance with our poor biddies, and see if I can not fix a place for them to lay. Huber and I will manage it, you know, and then he and I will gather the eggs, and won't we have fun? If they were not so far away, we would just carry a steam-pipe from the engine down there to warm up their quarters and cook their grain, boil potatoes, etc. Now, I have told you all about the Michigan State Convention, except the bee part of it, and this article has got to be so long that I think I will tell that next time. Lest somebody should complain that I have talked so much about this visit, we have put in four extra pages, as you will notice. I usually get talkative in the month of February, and find myself obliged to put in a leaf or two; but the spell seems to start earlier this winter. I do not know where we shall be by February, if I do not wind up; so, good-by until next time.

Oh yes! Before I close this paper I must tell you one other little circumstance. After I started home from Lansing, the bee-keepers who happened to be on my train of course knew me; and after we had gone a few miles a man of about my age came and introduced himself, and pretty soon asked me to come over to the other end of the car, where his wife was. I pretty soon discovered that, if I did not know them, they knew all about me. They were Mr. and Mrs. O. J. Bedell, of Kawkawlin, Mich. They have taken GLEANINGS almost since its commencement, and I soon realized they were not sorry either, by the kind compliments they paid it. They have succeeded with their bees, and their success has been mostly due to GLEANINGS. Now, I do not wish to have you think that they follow all my directions because they said that. They do not use the Simplicity hives nor frames, but a frame that friend B. contrived, after a notion of his own. The way he makes his honey-boxes is so unique that I think I shall have to tell you all about it. He goes out into the woods and hunts up a nice straight-grained pine-tree, just to suit him. This is cut, and made into plank. The plank is then cut off into bolts just as long as his sections up and down. Then these bolts are sliced up with a circular saw so as to have pieces

about $\frac{1}{2}$ inch thick, $4\frac{1}{2}$ inches long (that is, for Simplicity sections), and $14\frac{1}{2}$ inches wide. You see, it is a strip of board, as it were, with the grain running crosswise; and not only must the grain run crosswise, but it must be straight across, so you could take a knife and split up this board into strips, and have the strips split right square across, every time. These pieces are for a series of section boxes, something on the plan of the "Farmer" honey-box, only it does not have saw-cuts where the box has to be split. The top and bottom bars of the sections are, if I remember correctly, pieces sawed from $\frac{3}{4}$ -inch lumber, and thick enough to hold a nail. With some wire nails the thin boards are nailed into the end of the top and bottom bars, and these top and bottom bars are, from center to center, the width you wish to have your sections; that is, if you want 2-inch sections, you nail them 2 inches apart from center to center; for $1\frac{1}{2}$ -inch sections, $1\frac{1}{2}$ inches from center to center. Four of these long series of section boxes cover the top of the hive, and when they are filled they are carried to the grocery in that shape, and the grocer with his penknife splits off one section, or two together, or three, as the customer may wish. The wood being nice and straight-grained, as I have explained, they usually split pretty easily and true. Of course, no separators are used.

I can not remember how many bees friend B. keeps; but he took a little book out of his pocket, and showed me how much money 40 acres of wheat had brought him this season. I think it was somewhere about \$600. Right below he had added up his honey, and the honey had brought more money than the 40 acres of wheat. "Yes, Mr. Root," said he, "my honey crop has for a good many years brought me more money than all the rest of my farm together."

During the talk his wife shyly ventured the remark, that she had often heard her husband say he would give more to see me, and have a good talk with me, than with any other man in the world. And there I had been sitting all by myself in that car, and, I fear, holding myself aloof from the rest of the world, from a sort of foolish bashfulness, and, in fact, making myself so hard to get acquainted with that this good friend had to take some little pains before I could get it into my head that it was in my power to make them very happy by being sociable and friendly, just as I am here at home. There are seven juvenile Bedells in that Michigan home, and very likely they, too, have learned to love GLEANINGS. Mrs. B. made the remark, just before they had to leave the train, that she turned to the Home Papers the first of any thing in the journal. Said I, quickly, "With your family of seven children you are both united to some of our various churches, are you not?" But they were obliged to admit that they were not. I can not remember what friend B. said here, but it was something to the effect that he believed in Christianity and in the Savior, as I had presented it through the Home Papers. Is it really true, that such sacred responsibilities are resting on my poor self—that through me others are catching glimpses

of eternal life and the home beyond? If so, may God in his great mercy help me?

HEDDON'S FEEDER.

IS NOVICE FAIR?

BRO. ROOT:—Are you not mistaken or unfair, or both? You ask us to, and I will criticise you kindly. Our feeder-bottom is not "grooved" at all. Every thing is decently fitted, and solidly and plainly nailed together. About three in a hundred leak, and these we exchange and fix up, and that ends it. You say that my feeder seems to be a large Simplicity feeder. Now, this is not just, for inasmuch as they are alike, the Simplicity is a small Heddon feeder. Over 12 years ago, and I think before I ever heard of warbling-slots in which to put liquid feed where bees could get it and run no risk of drowning, I made these very slots, and used them for open-air feeding. Very soon after, I made, used, and sold feeders with these same slots, with reservoir at the side, and entrance at the bottom, operating throughout on the same plan as does the one shown on page 834, only it covered only one-fourth part of the hive, and was all in one piece. That feeder was made, used, and sold years before Mr. Gray invented the Simplicity, was it not? And if I understand your Simplicity cut and description in your circular, you come in contact with the bees when refilling. That we do not, I consider a very important point. I, too, used a glass cover, but used a wood cover over the glass, to shut out light. I am opposed to feeding at the entrance. I don't think any one will practice it, after using a good top feeder. You also say we leave a " $\frac{3}{4}$ " space between the climbing partitions. No, it is only about $\frac{1}{4}$; $\frac{3}{4}$ would be too large. All $\frac{1}{4}$ spaces will admit of the passage of bees at one time and one place, through it. A bee crawls back down as well as back up. This $\frac{1}{4}$ space "over the scant partition" is also a $\frac{1}{4}$ space under the cover, and more bees than five swarms would contain would never crowd this passageway.

"OBJECTIONS."

That these feeders take up some room is true of any feeder, and they dispatch work in a greater proportion than they take up room, as compared to other feeders. One feeder will feed ten different colonies, in a fair season of time. No trouble about warped covers. We don't make a cover that will warp badly enough to let in a bee. Another point is, we don't let our colonies "get a going" robbing; and if they did, they would never raise a light cover—at least, our covers are "light," and I never yet saw one rise, and in two instances by a new hand putting on old, rejected, and warped covers (of a style we do not use), the bees did get started pretty well on two feeders; but by closing the crack with our regular covers, all was again harmony; for, get in at the top they *couldn't*, and that had attracted their whole attention, so they never tried the entrance. This is one reason why I so dislike feeding at the entrance. We know by experience, that warping covers are not one particle of objection.

Now, about the food "spouting up," and rising and daubing the bees. I have tested this a few times by removing the cover and watching the action, and I never yet saw a bee get his back wet. I have seen a few with their legs and under-side wet;

but of the hundreds of feedersful we have fed, we have never seen one bee that looked honey-soaked, and this is more than we can say of any of the other feeders we have used much.

Dowagiac, Mich., Dec., 1884. JAMES HEDDON.

I don't quite see where the unfairness is, friend H. I said it seemed to me it was a large Simplicity feeder with additions, etc. I used the Simplicity for illustration, because everybody knows the principle of it. The Simplicity was first made by myself, and not by Mr. Gray. I supposed by the looks of the joints, that the bottom was grooved on to the sides and ends, so I shall have to give your workmen credit for making good joints. Feeders made of wooden boxes nailed together have so often given trouble, sooner or later, that I do not believe I shall want to use them. It was mainly for this reason I started making the Simplicity of a single block of wood grooved out with a gang of saws. Very likely your covers do not make trouble by warping, but I think it is because the workmanship is done under your own eye; but where covers are made in that way by the generality of mechanics, or even bee-hive manufacturers, I should think there would be a good deal of trouble in order to get the stiff rim to hold the cover-boards from warping, or getting on a twist.

INTERNATIONAL BEE-KEEPERS' CONVENTION

At the Exposition in New Orleans, Feb. 21, 25, and 26, 1885.

SOME SUGGESTIONS TO THE BEE-KEEPERS IN REGARD TO GETTING THERE.

AS it would be pleasant, if not profitable, for a lot of us to make this journey together, I have desired my friend Mr. Holmes, whose business is in this line, to tell us something about going all together. As there are low local rates at which tickets are sold from almost every neighborhood, the only way in which the thing can be managed is to have us meet in Cincinnati, say on Monday evening, Feb. 23. If we take the train then we shall reach New Orleans on the morning of the 25th. Of course, it would be desirable to be present on the 24th; but to do this we shall have to make the trip the week before, or travel on Sunday, either of which would be undesirable, for myself at least; but I submit the matter to the friends. In regard to the return trip, I for one wish to visit the Mammoth Cave, as alluded to in the postscript. Below is the letter from Mr. Holmes:

A. I. Root, Esq.,

Editor *Gleanings in Bee Culture*:

Dear Sir:—Allow me to call your attention to the Louisville & Nashville Railroad as a direct and very pleasant route for the bee-keepers of the United States and Canada to take when they go to New Orleans in February, to hold their convention, and visit the World's Fair and Cotton Exposition, starting from Cincinnati, and passing through Louisville, Nashville, Decatur, Birmingham, Montgomery, Mobile, and along the Gulf Coast to New Orleans. All railroad companies sell tickets via the L. & N.

R. R. via Cincinnati or Louisville; and if you can set the day to center in Cincinnati, and there are enough in the party to do so, I shall be pleased to reserve a sleeping-car for the bee-keepers from Cincinnati to New Orleans, which costs six dollars for a double berth, or twelve dollars for a section each way, or I can charter a car for you at one hundred and thirty dollars from Cincinnati to New Orleans, and you can divide the expenses pro rata between you all. By sleeping two in a berth, the car will accommodate 48 people; or one in a berth, 24 people, and this would certainly be the most pleasant way. You could all go to New Orleans, and get well acquainted; you can leave Cincinnati at 8:55 in the evening, and reach New Orleans the second morning at 7:50—a nice hour to arrive in a strange city. By their sending their names to you I will register them as received, and they would get their sleeping-car berths accordingly; but they must be sure their tickets read Louisville & Nashville R. R. from Cincinnati or Louisville to New Orleans. Any further information furnished upon application. Very truly yours—

HERMAN HOLMES,
Traveling Passenger Agent.

Medina, Ohio, Dec. 25, 1884.

P. S.—Those desiring to do so within the limit of their tickets, can stop off at Cave City, and visit Mammoth Cave on their return trip. H. H.

While I think of it, it seems to me every bee-man should wear a badge. I know a good many of us rather dislike this idea of advertising ourselves and our business. But when I attended our convention in Michigan I rode several long hours in the same car with at least two different bee-friends who were very anxious to see me, and I did not know them, and they did not know me. I have felt badly about it ever since. I do not see how we can find each other out unless we wear a badge. I did think once of standing up in the car and asking if any bee-men were present; but that would be a little out of my way of doing business, even though it might have been quite an accommodation to the friends mentioned. Let us hear from you who are expecting to go.

BEE CULTURE IN FLORIDA.

A VARIETY OF QUESTIONS, AND FRIEND HART'S ANSWER TO THE SAME.

QUESTION.—Will it pay for a man owning bees in the North to ship them to Florida, instead of purchasing there, if he intends to permanently locate South?

Answer.—If a fair price can be obtained for your bees there, it will not, as they can usually be got here at \$1.50 to \$7.00, according to strain of bees, quality of hive, and condition of colony.

Q.—When is the best time to ship, and would it be safe to ship in December?

A.—Sept., Oct., Nov., April, or May. I would not ship from there in December.

Q.—Could one who is an expert in the North, and can handle 200 swarms successfully for extracted honey, do as well with the same number of swarms in Florida, or would he have to learn so much about the climate, seasons, etc., as to diminish his yield?

A.—He could probably handle as many swarms in some parts of the State as he could North, after he

had got posted as to the honey-flows. Where he had plenty of black-mangrove bloom I think he would be compelled to keep less bees, or hire help, although his crop would probably be larger.

Q.—As you have no cold winters (which are a dread to me), what is the chief cause of loss of bees with you?

A.—I have not lost a colony of bees for years, except that two or three went to the woods two years ago. Death of the queen at a time of year when we are not watching the bees closely, has been the cause of losing two or three colonies in years past. In that case, simple neglect was the cause. We have all the enemies, and none of the diseases of other sections. The mosquito-hawk seems to be the worst one, as it catches many young queens while out to meet the drones. Notwithstanding all the enemies, my bees are always strong, and always have given good results; 130 pounds average per colony being my lowest in seven years.

Q.—When do bees swarm there?

A.—In March, April, May, and July. It is usually easy to prevent swarming after May 1.

Q.—What is the soil of Florida?

A.—Most of it is poor and sandy; but as it is not "thirsty" or "leachy" it retains fertilizers well, and responds to them and to good cultivation wonderfully well. Our hammock (or hummock) lands are black and rich, and produce heavy crops of all kinds suitable to the climate.

Q.—What is the price of hive lumber, and is your pine suitable for hive-making?

A.—Good Southern pine, suitable for hive-making, costs \$22.00 per thousand at the mills. We also have some handsome woods suitable for sections, besides plenty of basswood.

Q.—Is there a factory for making hives and bee-keepers' supplies in your State?

A.—No. What we do not make ourselves, we order from Georgia or the North. W. S. HART.

New Smyrna, Fla., Dec. 12, 1884.

CIRCULARS RECEIVED.

For Chas. Kingsley, Benton, La., we have just printed a 4-page list of queens, fdu., etc.

A postal card price list has been received from Jesse H. Roberts, Keene, Wis. Comb fdu and queens a specialty.

We have lately printed for J. B. McCormick, Fredericksburg, O., some price lists of apiarian supplies, 4 x 6, tinted paper.

From J. W. K. Shaw and Co. Lenoireville, La., we have received a postal circular of the Home Apiaries of 200 colonies. Queens a specialty.

P. L. Vialton, Bayou Gault, La., has just ordered from our press his seventh annual price list of bees, queens, etc. The pages are the size of these.

A. T. Cook, of Clinton Hollow, N. Y., is having his annual seed catalogue printed here. It will go to press immediately after printing this number of *Gleanings*. The design is quite novel, and reflects great credit on friend C. Do not fail to send for one, if you want a good garden.

The Berlin Fruit-Box Co., Berlin Heights, O., send us a very interesting 4-page circular. Their specialty is sheet sections, and they are making splendid sections by the means, and are building up a fine trade. They claim to have wooden separators dried in a press, as nice and straight as tin. We have sent for samples.

Mrs. Cotton sends out a circular for the fall of 1884. It is much like former circulars. She still insists that bee-journals and supply dealers have a spite against her because she is doing so much business. Her prices are somewhat reduced, and the "drawings" that were shown up so fully last season are offered for only \$3.00. There is one clause in her circular that seems to me to have the right ring to it, and I hope that those who deal with her will follow it out to the letter. It is as follows, verbatim:

"NOW I appeal to the honest intelligent Bee-Keepers of the country to give their testimony. I EARNESTLY REQUEST each person who orders of me at any time anything offered in my circular, to write on a postal card their experience in dealing with me. Please state plainly and in as few words as possible, just what you think of what you have received for your money, and send the postal card to the publisher of the publication in which you saw my advertisement."

"PLEASE BE SURE TO REPORT AS REQUESTED, for by so doing you will aid the right against the wrong."

DRAGON FLIES.

WHERE THEY COME FROM, AND WHAT THEY DO;
ARE THEY DANGEROUS?

FEW insects are better known than the dragon-flies, or "devil's darning-needles." In nearly all countries, various absurd powers have been attributed to them, and they have received popular names. The Germans, more poetical, in this respect at least, than their American cousins, call them "Gauze-flies," or "Virgins of the water," while the French gallantly style them "Demoiselles." A noted entomologist has affirmed these insects to be "the very incarnation of ugliness, and the perfection of all that is hideous." If he refers to their immature stages he is doubtless correct; but, few species of insects are more distinctively beautiful than some of the dragon-flies in their perfect state. For dazzling metallic luster, what can surpass the eyes, wings, and body of the blue-green species which flits irregularly about the fields and woods in June and July?

OUR OLD FRIEND THE DRAGON-FLY, OR "DEVIL'S DARNING-NEEDLE."

The eggs of these insects are deposited just beneath the water of ponds, creeks, etc., on the stems of reeds, and other aquatic plants, being held by a kind of glue with which they are covered. The young dragon-flies which hatch are handsome only in the sense of "handsome is that handsome does." They are great tyrants, killing all weaker brethren, such as the larvæ of mosquitoes, flies, etc., which cross their path. These larvæ are very active, and have a peculiar apparatus in the posterior end of their body, which serves for both locomotion and respiration. By means of tubes, the surrounding water is alternately drawn in and forced out, a process which may easily be seen by confining one of the little "beasts" in a glass aquarium. After living a short time the larva becomes a pupa, a state which corresponds to the chrysalis state of the butterfly, except that the dragon fly pupa is active.

When ready to assume the winged state, the insect crawls above the water on some reed or grass-blade, and the back of its pupa skin soon splits, out of which the dragon-fly crawls, suns itself for some time, and flies away. Tennyson beautifully and accurately describes this phenomenon thus:

To day I saw the dragon-fly
Come from the well where he did lie.
An inner impulse rent the veil
Of his old husk: from head to tail
Came out clear plates of sapphire mail.

He dried his wings: like gauze they grew;
Through crafts and pastures wet with dew
A living flash of light he flew.

These adult dragon-flies are considered very beneficial, because they devour myriads of gnats, mosquitoes, and other "small game." Sometimes they vex the apiarist by pouncing, falcon-like, upon his honey-laden bees as they homeward fly; but this is only true of the larger species. When they are numerous, and destructive enough to do serious injury, they should be captured with a butterfly net—something, however, which is easier said than done. To catch them, stand still and try to cage them as they flit past you; do not chase them, as they will rise and escape. CLARENCE M. WEED.

Lansing, Mich., Oct., 1884.

The opening of your remarks, friend W., reminds me vividly of the stories I used to hear about these snake-feeders, as we called them. Whenever one buzzed around our heads, instinctively both juvenile hands were clapped over our ears, because we had been told they sewed people's ears up with that long darning-needle body of theirs. I know they are handsome, but their gaudy beauty is so suggestive of stinking ponds and streams that I do not believe I shall ever admire them as I might otherwise. I am glad to know more about them than I ever did before. The complaints of their preying upon the bees have come mostly from the South. I do not think they do it—at least not very much, here in the North. I have seen them in that queer operation of laying eggs under water, but I never understood it before. Of course, they have some kind of a water-proof glue to make the eggs stick, and one falls to wondering how it is that they make it work right straight along. If some man had invented such a craft, think of the years he would need for experimenting to get it to work right along every day, without getting "out of kilter." "How wonderful are thy works, O Lord!"

SOME KIND WORDS FROM TOUNGOO, BURMAH.

FRIEND BUNKER TELLS US SOMETHING ABOUT
THE BEES THERE, AND GIVES SOME ENCOUR-
AGING WORDS IN REGARD TO THE
WORK OF THE MASTER.

YOUR beautiful A B C book reached me in good season, and on a recent tour among the churches and schools I took occasion to read it, and I must say I have been intensely interested in it. Some parts I have read repeatedly, and with great profit.

In some respects your work (the spiritual part) reminds me of my own. I, too, have a great factory. I will try to send you a photograph of it by and by. In this factory I have at present 160 girls and boys, and we are laboring, by God's help, without which we fully realize that we can do nothing, to make these boys and girls over from heathen members of society into good citizens, and, better, into skilled teachers and preachers for the millions of their countrymen, all over these hills to our east and north, to Thibet. This work you can have as little idea of as I do of your bee-keeping and factory. We work through this school as a means of influence on the 70 odd churches and stations all over these hills. Every church has its school, and gets its teacher from this school. Now, I see you have an immense work to oversee. I like your system very much; without it you could not ask success of

the heavenly Father. I can understand your care, your solicitude for the men and women, boys and girls, under your care; for do I not experience it all in *my* factory? These churches and schools, all branches of the great factory, the home factory with all it means, enables me to see your care. But, friend Root, I think we have some cares you can hardly expect in your work. You have men more or less fitted to your hand. We get material from the wildest of nature's children. Sometimes I think that *gratitude*, as the name, has no place in the hearts and language of these peoples. Your noble helpers *help* you; and even the material *you* work on, I see, often remember you with thanks. But, did you ever think how hard it would be to labor on years without one "thank you"? The other evening, about 9 o'clock, as I was retiring to rest, all tired out, I discovered, providentially, that my whole factory of boys and girls, with a very few notable exceptions, had quietly packed up their books and clothes, preparatory to leaving secretly by moonlight, say 4 or 5 o'clock in the morning, and all because I had called the school to account for breaking a rule forbidding them to go out among the Burman heathen, where they would learn all sorts of evil, in the *evening* time; i. e., without permission from some of the teachers. There were orphans among this number whom I had saved from death by starvation, and had fed and clothed for years. There were boys who had been in the theological seminary at Rangoon, studying for the ministry. There were none of the whole company who had not received aid and love and kindness from us in many ways; yet in a sort of panic of evil-heartedness they were all ready to break up their school on the slightest provocation.

I may add, that there was not one who did not afterward acknowledge that he was wrong, and ask forgiveness for what he had done. Your blessed Huber cheers you after your work is done. Bless the boy! *my* darlings are in far-off America, and I have not seen them for over four years. But I won't say more, lest you think I am *complaining*, which I am not. I merely speak of these things so that you who have already shown so much kindness and thoughtfulness for this far-off worker may the more intelligently pray for us that our strength fail not.

Notwithstanding what I have said, and much more of the same sort, I believe that the spirit of God is able to lift this people; that the Holy Spirit can and does convert their souls, and will lift them into civilization. I may not see a great advance in my life; but it will come, for the "Lord hath spoken it." We here have to fall back and rest entirely on the promises, after working on in the dark for years; but the promises of God are yea and amen. I have been struck with the similarity of our work, after all. They touch in many points. Allow me to say, that that 10-minutes' prayer-meeting at noon in your establishment gives me more hope and joy than all else in the book. It is, by God's grace, the key-note to your whole work, and your success is sure.

As time permits, I have been sucking in bee-knowledge. Perhaps I shall get a little time in the opening of the honey-season here (after the rains) to experiment. For this purpose I have sent an order to you. I wish now I had ordered more hives. I had not then learned the price. It would cost me here five times as much to make a Simplicity hive

as it would to order from you in America, ordinarily. Carpenter work of a good sort is very high and very slow. At best it is poor. If I can start two or three of my best Karens in bee-keeping I can help them very much, and perhaps the art of bee-keeping in the country. I shall be happy to do good in any way I can. I am here for that purpose. I suspect I shall have to send you larger orders as I get experience. In any case, with God's blessing I'm bound to make this go.

You see, I've caught the fever, and such fevers run with me usually till I win success or decided failure. My letter in GLEANINGS has stirred up several to write to me for queens! They want them sent by express. Why, there is no express within hundreds of miles of where I am. To reach Rangoon, the nearest sea-port town, we must take a native boat, a very rude affair, and go by the winding river nearly 200 miles. This a hot sickly country, away back among the ages of the Philistines, save where English enterprise has pierced this gloom of ignorance and superstition. To get a queen from Toungoo, after we had her caught and caged, would cost hundreds, and perhaps, I had almost said, thousands of dollars to get her home safely. At least, it would take the salary and expenses of a skilled bee-fancier to get bees from Burmah to America.

By the way, I saw in a recent GLEANINGS, under the head, "Notes from Burmah," something like it, concerning bees in Singapore. The fact is, Singapore is some 600 miles south of the most southern point of Burmah. Burmah is divided into two provinces—upper Burmah, and English, or Southern Burmah, the most southern point of which runs down on the Malay peninsula as far as Victoria Point, opposite an island of that name, at lat. 10° north. The dividing line between Burmah and Siamese provinces is the water-shed running north and south. This line runs down the Malay peninsula to lat. 10°, when it turns to the west, and strikes the point above named. As to fact, I have yet to learn that there is one hive of bees kept in any scientific way in the whole province of Burmah. There are wild bees everywhere, and on a bright day their hum fills the air, and swells to a roar on the grand old trees covered with bloom, till they look like a bouquet of the giants, and sicken the air with the richness of the perfume.

There, I didn't intend to write so much when I began; but we see few of our kind, and it's a relief to talk to some one who can sympathize with us sometimes. This, of course, is not intended for publication.

A. BUCKER.

Toungoo, Burmah, Sept. 26, 1884.

Why, friend B., do you say, "Of course, not for publication"? Your letter has cheered and encouraged me greatly; and do you not know there are hundreds and thousands who read GLEANINGS who are toiling, many times amid darkness and discouragements, in the same way you and I are? Don't be afraid to let your light shine, my good brother, and don't be afraid to ask us to pray for you when you feel weighed down by many cares. We rejoice at the opportunity, and daily prayers go up from many homes where GLEANINGS goes; and I am sure these prayers will be as an amen to my own prayer, that God may bless you and your flock away off across the ocean. We are intensely interested in your little story; but I watched all through your letter to have

you tell us more about what kind of occupation you furnish to those under your charge. We know about the schools and churches; but, what industry or industries do you take up?

PREVENTING SUGAR SYRUP FROM CRYSTALLIZING.

SOMETHING ABOUT TRANSFERRING IN WINTER, ETC.

I HAVE just been reading an article in GLEANINGS on "Crystallizing of Sugar Syrup." I see it is claimed that it will crystallize—as a rule—only when made too thick. Further on, in the same paragraph, it is suggested that crystallization probably took place—in a certain instance—because "he put in too much sugar for the quantity of water."

So far I have found it impossible to thoroughly dissolve the sugar unless I use water enough to make the solution quite thin—too thin for feeding. Hence I can not succeed in making a syrup that will stay syrup, without boiling.

Years ago I worked in a candy-factory, and there I learned, that when transparent, or "crystal candy" was to be made, the sugar was boiled down from a thin solution, over a charcoal fire, without any kind of stirring. Now, I never had occasion to make the experiment, but I believe that, with some less boiling, this candy syrup would have remained syrup. Stirring the sugar until thoroughly dissolved, immediately after the water is added, has nothing to do with its crystallization; indeed, the sugar will settle to the bottom, and harden, unless it is thoroughly incorporated with the water by agitation of some kind. But, let it be remembered, after this point is reached it should be boiled without stirring, and, when done, left standing in the vessel in which it is boiled, until needed.

I have tried the "honey" by adding about one-sixth to the sugar; and I am well satisfied that it will prevent granulation—or crystallization—better than any thing else, and certainly without risk of injury to the bees.

Very good, friend G. But if honey effectually prevents crystallization, what is the use of going to the trouble of boiling it? Just pour boiling water on your sugar, put in the quantity of honey mentioned, stir it thoroughly, and there you have it, without taking the stuff near the stove at all. If I am not mistaken, your wife will be on my side every time.

One of my hives, containing a very strong colony, and having ten frames full of honey (mostly unsealed) was upset one night late in October, by a "nasty hog." That accident necessitated a careful overhauling of the contents of the hive, and the feeding of 12 lbs. of syrup, to make up the loss. But the colony seems to be none the worse now for the rough treatment.

December 5th I transferred a swarm of bees from a barrel, in which they had been keeping house since June last. I found not less than three gallons of bees, but almost no good honey in the combs, of which the upper half of the barrel was full. I have them in a twelve-frame hive in the cellar, and have given them 20 lbs. of syrup since they were transferred. To-day, Dec. 16, they are well and apparently happy in their new home. My bee-books and bee-journals gave me not even a hint as to whether

such a job might be done in December or not. But, the wise hen cackles *after* the egg is laid. You will probably want to hear about this transaction again next spring; and I may have cause to wish I had said nothing now.

J. D. GEHRING.

Parkville, Mo.

I think your winter transferring will turn out all right. Of course, we should like to have you report in regard to it; that is, if the bees you transferred die, and those that were not disturbed come out all right, it will be rather against winter transferring. I shouldn't wonder, however, if the colony that had the 20 lbs. of syrup in December would be ahead of the others. I do not think there is any difficulty about transferring in winter, if one understands his business.

A LOCALITY WHERE THEY LIKE HONEY-DEW.

SOMETHING IN DEFENSE OF THIS KIND OF HONEY.

FRIEND ROOT:—I am a constant reader of GLEANINGS, and like it very much. I have read many articles in it the last few years about honey. Now, we have not had the opportunity to study the matter closely, but take honey-dew as a gift from above, and like that grade of honey very much, and so do our customers. After buying it once they will call for it again. Three years ago our honey-dew honey took the second premium at the Inter-State Exposition at St. Joseph, the honey being in 10 lb. boxes, while the honey in competition was of different grades, and in one-pound sections. It was darker than clover honey, but was pleasant to the taste, and of fine flavor. If the aphides produce honey, do they not first eat it? If they puncture plants, and cause it to flow from the plant or tree so punctured, why is honey-dew found upon leaves of trees that produce a bitter instead of a sweet taste, as the oak-tree? Why is honey-dew found mostly on the topmost leaves of the trees, and not on the lower ones? Why do we never have honey-dew unless there is a great flow of honey from flowers? and why do we never have honey-dew unless accompanied by heavy dew? We think that the position taken in GLEANINGS in regard to honey-dew is detrimental to the sale of honey in general; for people don't like to eat "bug juice."

Bees have not done well here this season, scarcely yielding 20 lbs. to the colony; spring court. The basswood was an entire failure, as was also the goldenrod. Some colonies are short of winter stores, and will have to be fed. The spider plant produces honey from the first of July until the 25th of October, standing the dry hot weather and three slight frosts without checking the honey-flow.

MRS. J. W. THORNTON.

Stewartsville, Dekalb Co., Mo.

I do not think the aphides eat honey, my friend, but, rather, that they eat the leaves and suck out the juices by puncturing the bark. These juices and the foliage are perhaps largely made up of starchy matter, and the aphides convert the starch into sugar, and exude it. This exuded sweet substance falls on the leaves of the trees; and where it is on the topmost branches, I think we shall always find the aphides on the foliage above

it. I believe we have honey-dew honey here when there is no flow from the flowers at all, as has been the case this season, when the honey-dew came during the extreme drought. It needs the honey-dew or rain to soften up the dried-down saccharine matter so the bees can lick it up. May be you are right in thinking we had better stop calling it bug juice. There is a great difference in the quality of the honey-dew, and we have some around here who like it, and prefer it to any other honey—not enough, however, to make a market for it. A man was here yesterday with over 500 lbs. of beautiful-looking white comb honey stored in one-pound sections. I did not dare offer him even 10 cts. per lb. for it, for the reason that I have been unable to dispose of the whole of a 48-lb. case, although I sell it as low as 12 cts. per lb.

SUGGESTIONS IN REGARD TO AN APIARY, AND A SHOP FOR MAK- ING BEE-HIVES.

ABOUT SUCH AN ESTABLISHMENT AS EVERY SMALL
TOWN OR VILLAGE SHOULD CONTAIN.

FRIEND ROOT:—I send you by mail six cards, with some photographs on, of bees, etc., not to have engravings made, but as a sort of visit to you to this part of the country. If there is any thing in them that you wish to have engraved, you are welcome to do so. The cut of drone in GLEANINGS, Oct. 1, is a very good representation of the photograph I sent you, so I suppose it was made from it. I believe I am already paid, as I received a photograph of A. I. R. free by mail for my album about that time.

Careless bee-keepers in this neighborhood are losing some colonies by starvation, as the crop was short, and the bees kept breeding so much all through the season. JAS. A. NELSON.

Wyandott, Kansas, Oct. 28, 1884.

The engravings on the opposite page were suggested by some stereoscopic views kindly sent me by Mr. James A. Nelson, of Wyandott, Kansas. You see friend Nelson, in his letter above, says I may make what use of the drawings I choose. Well, I believe the two pictures are not very far from the photographs, but I have changed them a little in some of the details. I do not know whether friend N. lives in a village or a town or a city; but in looking at the pictures it occurred to me that every village could with profit afford something like the bee-hive shop shown. The machinery, indeed, could be run by horse-power, tread-power, wind-power, or, perhaps, best of all, a little two-horse-power engine. The engine, to be out of the way, can be in a sort of shop, or lean-to, against the building. A suitable opening in the wall should be provided at the proper place to push through shavings and refuse lumber. For safety in case of fire, I would have this opening closed by a swinging door, the latter being covered with tin, as well as the woodwork around the engine and boiler. The shop should be long enough to handle 16-foot boards nicely. There had better be two saw-tables—one for cut off, and the other for rip, although one table may be made to answer both purposes

for a time; in fact, by frequent change one table may be made to do almost all the work. For making sections, a gang of dovetailing saws will be needed; and if one-piece sections are to be made, it will take still another machine. The machinery should be chosen, of course, according to the amount of work to be done. If bee culture is in its infancy in your vicinity it would not pay you to make any great outlay to begin with. Now, the great secret of succeeding in business will be to have every thing that anybody may call for, in readiness to load up on the instant, in case your customer is in a hurry.

In the foreground we notice a friend who has probably loitered into this shop to see what is going on there. He naturally asks about honey; and probably somewhere in the rear of the shop, near the apiary, he has been shown honey nicely put up, neatly labeled, in tin pails of various sizes. May be some of them are out on the walk. He tastes it leisurely, after awhile takes out his pocket-book, and pays for a painful, such as he thinks will be needed for the family.

The man with the wheelbarrow owns a grocery, and he, too, has been attracted by the look of thrift and business that is seen around the establishment. He has taken a 48-pound case of comb honey, and also a combined crate holding a single tier of sections. The latter he has set up edgewise, as you will notice. If he has good luck he will come around with his wheelbarrow often, you may depend on it.

The fellow who owns the horse and wagon, and looks after the happiness of that nice little woman with a parasol, is a farmer. Said little woman took a shine to bee culture, as many a thrifty housewife does; and one day, when they were busy cultivating the corn, she spoke something as follows:

"James, our bees are doing so well I am really afraid they may possibly swarm; and you know you have not got those new hives that you promised to see about."

He stands with both hands straight down, looks anxiously at the corn-field, and then back to his trim little wife. She is a pretty good general, and knows how to manage not only bees but husbands, so she tips her shapely head a little to one side, and then with a smile she knows he can not resist, suggests, "I should really like to go to town this morning, and you know it would not take any more time now than after the bees have swarmed; and then may be they would be gone to the woods before you got back, if you did that way. It would take you but a little while, and I will be ready just as soon as you can get hitched up."

You see, the conversation has all been on one side. James, like a dutiful husband, just let her do the talking, and before nine o'clock this bright June morning there they are at the bee-man's establishment. I suppose he has got boys enough to run the buzzsaws while he sees to the hives, and loads them up; so there he is with his coat off, explaining matters. I do not quite see what is to be done with the little woman, if you put many more hives into that light spring buggy; but I guess they will fix it safely. When

VIEW OF THE APIARY IN THE REAR OF THE BEE-HIVE SHOP.

VIEW FROM THE FRONT OF THE BEE-HIVE SHOP.

two young people start out in the world to make a success of life they can get along a good deal cramped up for a little while, and they will also manage to get a good deal of stuff into one small wagon. Well, well; if they are agreed, we are.

Let us now look into the back yard. Although our bee-man is a hard-working fellow, he has had time to make friends with not only the grocery-keeper, blacksmith, harness-maker, and the rest of the mechanics of his town, but he is also on good terms with the doctor and lawyer. In fact, these two worthies have been long his best customers, and done much to introduce his honey. The minister has been among his customers too, even if he *didn't* pay for the honey in dollars and cents. Well, the people around town are so proud, the most of them, of the establishment in their midst, that when a distant friend comes to see them, they must take him over to see what is being done with bees. And that is the doctor now explaining to that chap with the cane, how this man is prospering and building up an honest business, while the neighbors around them tell stories at the grocery, and smoke their pipes. This doctor does not use tobacco. In fact, I have been told there are a good many of the doctors who are following in the wake of the young ministers. In setting a good example in the neighborhood they seek to lead.

Now, if this story is an interesting one to you, and you want to hear more of it, just go and visit the man who makes bee-hives, somewhere in your vicinity. While I think of it, suppose you just carry this journal along and show him these pictures.

DEMORALIZED SWARMS.

ANOTHER PLAN TO MAKE THEM STAY.

I SEE IN GLEANINGS, Nov. 15, Dr. P. G. Aldredge recommends caging bees that will not stay in the hive, and you seem to think his plan is a good one, and so it is, no doubt; and as I am not much of a bee-keeper I shall not pretend to say that it is not; but if you will permit me, I will tell you how I managed such a swarm for a neighbor, the past season. They were a swarm of blacks that had been brought from the woods, and transferred from a tree into a movable-frame hive. They did not like their new home, for some reason, and would not stay in the hive. They swarmed out, and were returned to the hive a number of times, and at last refused to enter the hive at all, but would run out and cluster on the outside. At last I was called to help conquer them, and this is the way I did it: I first sprinkled the cluster with sweetened water; then I spread them out on a large cloth, hunted the queen, and caged her in a wire-cloth cage. I now suspended the cage with the queen from the top-bars of the frames in the hive. Having done this I placed the cluster to the entrance, when they went in with a rush. In 24 hours I went back to see how they were doing, and found the workers busy at work. I now liberated the queen, and had no more trouble with them.

Now, I prefer this plan for several reasons. 1. Because it saves feeding. 2. Because it saves time to the bees; the workers being at liberty, they will not only make their own living, but a good swarm can, in a week's time, have their hive half full of comb and honey, which they could not do if they were confined to the hive as the doctor recommends. J. R. CRIDE.

Lagrange Center, Ind., Dec. 1, 1884.

MICHIGAN STATE CONVENTION.

A REPORT FROM W. Z. HUTCHINSON.

FRIEND ROOT:—As you prefer that convention reports should be simply a summing-up, I will send you such a report of the convention at Lansing. Any points that are brought out sufficiently in your editorial upon the subject you can, of course, drop from this report.

REVERSIBLE FRAMES.

The idea of reversing frames seems to be gaining ground. Reversal secures the attachment of combs to the bottom-bars, and, if done at the proper time, the removal of the honey from the brood-nest to the sections, where it can be sold for twice what it will cost to buy sugar to put in its place. Sugar is a safer winter food than honey. Reversal secures a large amount of brood in a small hive. No device for reversing, yet given to the public, is free from objections.

ONE ENTRANCE.

And that at the bottom of the hive, is sufficient, even when hives are two or more stories high.

STARTING BEES IN THE SECTIONS.

If a colony is disinclined to begin work in sections it can usually be started by giving it two or three sections, with the adhering bees, from some colony that has commenced work.

DISPENSING WITH SEPARATORS.

To dispense with separators, use sections not more than 12½ inches wide, fill them full of fdn., and don't give too much room in the surplus apartment. The only apparent advantage in sections less than 12½ inches wide is, that the honey is ripened and sealed sooner. One-pound sections appear to be the most profitable size to use at present.

THE HEDDON CASE

For holding sections on the hive received a regular "boom;" all who had tried them were enthusiastic in their praise. They can be used without a honey-board; but one is needed to keep the bees from building brace-combs between the sections and the brood-nest.

QUEEN-EXCLUDING HONEY-BOARDS

Are a convenience, and save much annoyance; but they can be dispensed with. If it is desirable to "squeeze" the honey from the brood-nest into the sections, or to have bees upon empty frames or fdn., and give sections at once, then they are needed.

SECRETION OF WAX.

Prof. Cook is positive that bees do not secrete wax unless they have use for it. He had, however, conducted no experiments exactly similar to those made by myself, but thought the increased amount of surplus apparently secured by not using fdn. in the brood-nest might have been the result of the honey being stored in the sections instead of part of it being put into the brood-nest. I shall try more conclusive experiments another season.

GETTING BEES OUT OF BOXES OR CASES.

Drive down as many as possible with smoke; if strong enough, shake out nearly all of the rest, and then carry the cases into a honey-house or tent, from which, the few straggling bees can escape through an opening over the window, or in the top of the tent. Another plan is to set the case down on end in front of the hive, and, with smoke and a bunch of June grass, drive out what bees remain. The "calling" of the bees at the entrance of the hive entices the bees from the case.

PREVENTION OF AFTER-SWARMING.

The Heddon method was described. It consists in having the prime swarm in a new hive upon the old stand, and setting the old hive a few feet to one side until the newly hived swarm is nicely at work, when the old hive is placed by the side of the new one, with its entrance turned to one side at an angle of 45°. Each day the entrance of the old hive is slightly turned toward the new hive until the hives stand in contact side by side. At the 7th day, move the old hive to a new location. If placed at the end of a row of hives there is but little danger of queens being lost.

CARNIOLAN BEES.

These resemble the German variety, are good workers, good comb-builders, very prolific, and inclined to swarm, and the gentlest bees known.

THE POLLEN THEORY.

That the consumption is the immediate cause of dysentery among bees, there is little doubt. Mature bees *do* consume pollen, even when not rearing brood. Analysis and microscopical examinations show the excreta of bees to be largely composed of pollen. Bees *do not* void their feces in a dry state. Dysentery has been produced by giving an abundance of pollen, and prevented by removing it in the fall. The most *practical* plan of preventing dysentery appears to be the removal of the honey and pollen in the fall, and the feeding of cane-sugar syrup; but that bees sometimes winter well with pollen in the combs should not be forgotten; perhaps we can yet learn how to induce them to let the pollen alone.

PROTECTION IN WINTER.

Lessens the consumption of stores, and the more perfect the protection the smaller will be the amount consumed.

"NOTES FOR THE YEAR"

Was an essay read by Prof. Cook. Some of its points have already been covered in the discussions reported above. Among other things, he said that many bee-keepers were unscientific, and many of their statements must necessarily be untrue; as, for instance, the assertion that worker larvae turned to drone, or that the tissues of a drone-larva could fecundate a queen by being placed in the cell of the latter when it was in a larval state. We are not yet ready to shout "Eureka" in regard to phenol as a remedy for foul brood. The crossing of different varieties of bees ought not to be discouraged; our best breeds of stock were developed from a cross. By means of fdn., drone-traps, and attention to the kind of bees kept in the vicinity, the matter of crossing bees satisfactorily is not hopeless.

STATISTICS.

Bees, honey, and wax are not among the products reported upon by the crop correspondents, and the executive board of the society was appointed a committee to secure the legislation necessary to have apianian products added to the list.

DISTANCE APART FOR HIVES.

As a general thing, hives need be placed no further apart than is necessary to give room for working among them. In a queen-rearing apiary it is more important that the hives or nuclei be scattered about promiscuously, than in one run for honey.

RAISING NICE HONEY.

Upon request, Miss Wilkins told how she and her sister raised the fine honey that they do. They used the finest white-poplar sections, which they thought important. They used the Doolittle hive and sys-

tem of management. The sections were removed as soon as finished, and all traces of propolis carefully scraped away. The source from which much of their honey was gathered (willow herb) had much to do with its fine appearance.

TAKING BEES FROM THE CELLAR.

When bees are taken from the cellar in the spring it is not necessary that each colony should be placed upon the same stand it occupied the previous season.

ALSIKE CLOVER

Had been cut just as it was beginning to blossom, with the hopes that it would again be in blossom just after basswood, but it did not start again; the drought might have been the cause.

There were, of course, many details and minor topics, not given in this short article; neither let it be supposed that *everybody* agreed with *all* of the above conclusions; but, as far as I was able to judge, the majority agreed with them, and in some instances the decision was nearly if not quite unanimous.

There will be no State convention held in 1885, but the society will meet in conjunction with the North American at Detroit.

W. Z. HUTCHINSON, 68-94.

Rogersville, Genesee Co., Mich., Dec. 22, 1884.

FLORIDA.

SOMETHING FROM NEAR FRIEND HART'S NEIGHBORHOOD.

OUR experiment in bee-keeping among the pines of Florida has now covered about one year, and we can tell a little better what to expect in the future. Seasons will vary here as in other places, yet the main source of honey supply will not change much. The first of last December we had fifteen nuclei, 13 pure Italians and 2 hybrid. Two were lost in transit from Bonair, Iowa; have fed about 15 lbs. of granulated sugar. We did not dare to ship much honey with the bees, so they were short when they arrived.

We have taken nearly 700 lbs. of extracted honey; sold at 10 cts. per lb. except what has been used in the family. We sold \$18.00 worth of queens, and have now 18 strong colonies and 4 nuclei, all pure Italians. This, of course, is no great showing, nor is this a famous bee country. Bees gather a little pollen, and perhaps some honey, during every month in the year, but no surplus except in January, from scrub pine; in March, from orange-blossoms; and in May, from saw-palmetto. There is a great variety of flowers from January to November, and bees work on some of them, but not enough to much more than live. Palmetto honey is nearly equal to white clover. Orange honey is darker and not quite so good, but there is no honey that we have had that is so dark or strong-tasted as buckwheat honey. Bees swarm here on orange or palmetto honey. After the first of June, strong colonies reared a good deal of brood till October. Sometimes they would be nearly out of honey; but by October most of them had enough on hand to last them through. The small nuclei, however, had to be fed or strengthened from strong colonies, to keep them going. It is hard telling what they do live on. Corn-blossoms in their season help some, and field peas, which are raised here, keep them pretty busy. The bees would be very busy about the pea-vines, but not on the flowers. The glands,

or nodes, near where the flower stalks or peduncles grew, were haunted from morning till night. I looked in vain, however, for any full combs of honey. I found bees working on *Cassia chamaecrista* (partridge pea), which is very plentiful here; on *Palafioria integrifolia*, and on *Elephantopus tomentosus* (elephant's foot). For a long time the woods were yellow with many species of *Compositæ*, among the several species of goldenrod; only one, however, that I could find the bees doing any thing on—a coarse species of goldenrod (*Solidago pilosa*), which grew in low grounds. I saw my bees working on it very busily two miles from here, and think they would have done well on it if there had only been enough of it. There is not enough cabbage-palmetto near us for the bees to do much on. That yields a good deal of nice honey, but grows mostly on low ground, near rivers, hammock land, and near the sea coast. We came here on account of my health, and I think the only healthful places in Florida are on the high pine lands, several miles away from any river or hammock land, and away from any place where wells have to be dug through shell formations.

Eighteen miles east of us is Mr. Hart's apiary, near New Smyrna. There they have plenty of saw and cabbage palmetto; and the mangrove islands, when in bloom, rain down honey by the barrel full. I have been there several times. The mangroves are said to be limited to a few miles south of New Smyrna, and two years ago when I was there with friend Poppleton, from Iowa, we concluded that the bee business was about all monopolized. I believe Mr. Poppleton has since purchased land there; and if he settles there he will undoubtedly meet with success, as he is one of the most successful apiculturists that I have ever met. There is better soil at Smyrna, and plenty of oysters and fish, which are all much more desirable than the malaria, mosquitoes, and millions of sand-flies that can be kept out only by something as fine as cheese-cloth. Away from the mangroves, I know of no place in Florida where honey can be raised in such paying quantities as it can be in the North; yet any intelligent bee-keeper who comes here for his health, or to raise oranges, would, in my opinion, make a mistake if he did not keep a few colonies of Italians. In many places, pure mating would be a sure thing. Every queen raised in our apiary during the past season has proved to be a pure Italian. Two-banded bees are as scarce in our yard as three-banded bees are in the yards of some dealers. I once visited an apiary where there were only two or three pure colonies of Italians, in over 50 colonies; the rest were blacks and hybrids, drones flying from all, and yet the owner was advertising dollar Italian queens for sale (I believe he never advertised in GLEANINGS). There were two colonies of blacks near here, but I gave them two pure queens, and settled that business. The old settlers in this country know very little about bees. They call the queen a king, and think he rules the colony.

Twelve degrees above freezing is the coldest weather we have had yet. The weather averages, I think, between 60° and 70°, but gradually gets a little colder. We shall probably have frost in a few weeks. Last winter we had none till January. Sometimes, I believe, there has been no frost. Those who have ambition enough to plant and properly fertilize are now having good vegetables in their gardens. Cabbage, lettuce, radishes, beets,

turnips, egg-plant, tomatoes, and onions, will be all right till heavy frost kills the tender kinds. With a little protection they can be had all winter. Strawberries begin to ripen in January, generally, but seasons vary. Oranges and lemons are plentiful at \$1.00 to \$1.50 per hundred. The soil in all healthful locations is a very light sand, and will not produce much without fertilizing. People who have money enough to afford the trip, or who have bronchitis, catarrh, asthma, rheumatism, or dyspepsia, will be paid for spending some time in the pine woods of Florida. It is not a good place for a poor man.

GEO. W. WEBSTER.

Lake Helen, Volusia Co., Fla., Nov. 24, 1884.

KEEPING A SMOKER IN GOOD ORDER.

AN IMPLEMENT FOR CLEANING THE SOOT OUT OF THE AIR-TUBE.

AFTER using several kinds of smokers, I prefer the Clark to any other. I know some object to so much smoke, sometimes, when we don't need it; yet it does smoke when we do need it, and it just sends it off where we wish; and if we knock its nose against the hive or any thing, it doesn't fall apart and spill fire and the whole contents into the hive; and, again, it's so cheap that every one can have one, even to drive mosquitoes out of the house. Yet, like all others, there is a little trouble that I have for some time been studying on; that is, the wind-tube does, after a time, clog up with soot; and unless one gives it some attention and thought, he would say the smoker was good for nothing. Well, I tried a number of ways, and now I believe I've got what pleases me ever so much.

CHURCHILL'S IMPLEMENT FOR CLEANING SMOKER-TUBES.

Perhaps a wire of soft pliable iron may be better. I send you a sample, which is spring wire. You can clean out the tubes, also the nozzle of smoker. Please give it a trial; and if it is of any good in your mind, you can make as many as you wish (as it is not patented). You will see at once they cost almost nothing; but to me they have been worth a great deal, and what few have used them say as I do.

E. P. CHURCHILL.

North Auburn, Me., Nov. 5, 1884.

Friend C., you have indeed struck on something very valuable, in my opinion, even though it is quite simple. Our apiarist has tried it on the smokers he had in use, and he says that every Simplicity smoker should have one. We have ordered a lot of wire from the wire-mills, made just right, and will get out the necessary machinery for making them rapidly, and hereafter we expect to send one along with every smoker we send out. We credit you five dollars for the invention, and tender our thanks besides. Those who want one for smokers they already have in use can have them for 5 cts. each; 35 cts. for ten, or \$3.00 per hundred. If wanted by mail, 2 cts. each in addition, or 5 cts. for each package of ten.

HINTS TO THOSE WHO WANT TO BECOME PROFICIENT IN BUSINESS.

SOMETHING TO CLERKS, DEDUCED FROM 25 YEARS OF EXPERIENCE.

First Hint.

ORDER was heaven's first law, and it must be our first law here in the office: therefore each clerk is provided with a scribbling-book, and every mark with pen or pencil must be made in this book, unless it is made on the letter you are answering, as a note of what you have written to your correspondent. I have almost always had trouble in getting clerks to observe this rule; and then, I am sorry to say, new clerks are the worst, because they can not understand what harm it may do to make their computations on an old envelope or piece of paper picked out of the waste-basket, instead of making all their marking and scribbling in a book. One without experience can not tell how much trouble it makes in an office like ours, to have writing and figures on a piece of paper left on some of the desks. No one dare throw it away, for fear it may be important, and such scraps are sometimes kept around for weeks and months. For the same reason, I object to tablets. A book costs little more, and then any offer that has ever been made to anybody, or any figures that have been put down, can always be found, even if somebody should claim we had wronged him by an error, and should not make complaint until weeks or months afterward. Your computation or scribbling book should be dated, in order that you may be able to fix the date of any transaction, as we have mentioned, when called upon to do so. The pages should be filled close and solid, as far as you go—not only on account of economy, but that you may learn correct business habits. If you open the book at random, and scribble in it here and there, it is unsightly and untidy, and can not well be kept accurately dated. If I pay you for your time, it is my privilege to direct matters, and say how they shall be kept; and whatever marks or figures or writing is done on time that you charge me for, is my property. If I choose to have it preserved, it is my right.

Second Hint.—Provide yourself with paper-weights of some kind, and see that no loose papers are ever lying on the top of your desk. A gust of wind may sweep them off on the floor, and they be mixed up or lost. Have your paper-weights labeled, and keep them on top of the proper pile of papers or letters. Allow no loose papers a place on your desk, or in the drawers to your desk. In fact, keep no papers or property of any kind that you are not using or likely to use. Fight against accumulations of rubbish and dead property as if it were an insidious foe. Make every thing about you count somewhere, and keep it moving.

Third Hint.—If you spoil an envelope or postal card or sheet of paper, by no means waste time in tearing it up. It will be just as safe if you lay it quietly by in our waste-paper basket. I have seen a new clerk occupy considerable time in tearing a sheet of paper to pieces, and then throw it toward

the waste-paper basket, leaving the pieces to blow about the room; whereas, if it had been quietly deposited whole, it would not only have saved her time, but the clerk who cares for the room, in picking up the little bits. Our waste-paper basket will hold whole papers, but little pieces rattle through it.

Fourth Hint.—When you make a mistake in writing any word or figure, under no circumstances undertake to scratch it out with a knife or any similar implement. Cross it out with a pen, then put down the word you want. If you get a whole line wrong, cross out the line neatly. It is not necessary to make a great number of crosses, for such motions take time, and mar the beauty of your work. Draw two parallel lines across the error or line, and this will indicate to any reader that such portions are not to be read or considered. A single line across a word does very well; but it may be mistaken for the cross of a *t*, and therefore I would draw two parallel lines with the pencil, rather than cross each letter or figure. If you do not discover that the letters or figures are wrong until the letter has been written, after crossing out the word in the way I have indicated, put the proper word or figure just above the one crossed out. Under no circumstances make one figure on top of another. Expensive blunders and considerable quarrels have resulted because clerks persist in this very bad habit. Clerks sometimes urge that there was not any room to write the word properly, unless they scratched out the wrong one with a penknife. When you meet a case of this kind, please bring it to me, and I will show you how to fix it. Every clerk should be able to write a small plain hand, with the express view of being able to interline things of this kind when necessary. One great reason why we employ women to do writing, rather than men, is because they are usually taught to write a small plain hand.

Fifth Hint.—If you are not able to make figures so plain that no one can ever mistake one figure for another, set about doing it at once, and practice on them, and decide on ways of making them until you can do it so well that no one will say, during ten years of work, that he ever read a 6 for a 0, a 7 for a 1, a 2 for a 3, etc. You can practice making these figures in your computation-book, and I will pay you for the time of doing it.

Sixth Hint.—When you are intrusted with letters to answer, be sure that every question your correspondent asks is answered in some way or other. If he asks a question that is answered plainly in the A B C book, write him a postal card, telling him the A B C book mailed him covers the ground fully; and if you can, without great trouble, tell him what page in the book treats on the subject. If your correspondent asks for a price list, be very sure that he has one; and after you have sent it, tell him so. Never say a price list has been sent, because you are just going to send it. Accustom yourself to telling the exact truth in every thing you do. Many business men and women have crippled their money value by getting into this one habit of writing to people that things

are done, when they only mean they are just going to do them. Never, under any circumstances, say a thing is done until it is done. About three-fourths of the people who apply for situations will now and then forget to send a correspondent (and probable customer) a price list when he asks for it. I once sent to a large business firm for a price list of their machinery. They wrote me a courteous letter, saying the list had been sent. I waited several weeks, and did not get it. They wrote another courteous letter, with an humble apology for the clerk who should have attended to it, *and didn't send it then!* The third time I made out to get the price list, and sent them an order for several hundred dollars' worth of machinery. Many clerks seem to think it is a small thing to make a fuss about, because now and then they omit such a little item as mailing a price list; but after tracing the matter up, and finding the same clerk had done this two or three times, I usually say, with my past experience, that he had better be set to work somewhere where such mistakes would not do very much harm.

Seventh Hint.—When you write to a correspondent that something will be sent him, make it your business to inquire and understand how this promise is to be made good. Last summer we were, for a few days, out of A B C books; and as the friends were in a hurry for their goods, the shippers were instructed to send the goods along, and that the A B C book would follow at our own expense. Well, one of the clerks wrote this to a large number of customers; and as she was new in the business she supposed some arrangement had been made for mailing the books when out of the press, but did not inquire into it. The letters were distributed, and complaints kept coming for several months afterward, "Is it possible you have not got those A B C books done yet?" and such like statements. A search revealed the fact that the promise was noted on the back of the letter, but it was then distributed, and that was the end of it. Therefore, when you make a promise, make it your business to find out how this promise is to be kept, and do not rest satisfied until you know; for your own reputation, as well as your customer's welfare, is involved. These letters, after having been answered, should have been carried to the mailing clerk, to be placed under her weight, labeled, "Awaiting A B C books." The books have been piled up in the vaults several months, while these friends were watching the mails anxiously and patiently.

Eighth Hint.—Not only keep the top of your desk free from rubbish and accumulations, but be sure you know the contents of every drawer in your desk, and do not harbor any rubbish there. Be prepared, if possible, to answer every letter within a few hours after it has been put into your hands; and when you are done with it, push it forward quickly to the next clerk, as soon as possible. Some clerks will keep letters lying on their desks when it seems as if no one could read them without feeling touched at the writer's pleading to have his goods hurried along. I have found letters that had

been lying several days when the writer said, "Mr. Root, do not let a train leave after this gets into your hands, without putting my goods aboard;" and yet the clerk who had the letter in charge read it over listlessly, and laid it down again until two or three trains had passed. With the view of remedying this trouble, most of the desks are supplied with a weight, reading like this: "Immediate attention," and my instructions have been that *some sort* of an answer must be given to all such letters before another mail leaves the office. You may think this an easy thing to be managed; but, my friends, it is one of the hardest things to attain of any thing I have ever tried in my life. Even during the dull season, when clerks have only enough to do to keep them part of the day, they will let mails leave once and even twice before the paper under the immediate-attention weight has been looked at. One new at the business would say, "Turn them off and get better ones." I tell you, I have tried different people until I am sick and tired of it. The inertia of humanity, if I may so term it, seems to be the obstacle in the way, and it pains me to be obliged to say that men do not average nearly as well as women. In spite of every thing I can do they will answer letters and leave them lying just where they last had them. A man can not be made (so far as my experience goes) to be as neat and orderly and systematic in this question of work of correspondence, as a woman; and it is only once in a great while that we find a *woman* who is fully up to all I have mapped out heretofore. There are a *few*, however, and we sometimes find them where we least expected it. One whom the world has never noticed much, perhaps, and whom nobody would suspect of having rare business traits, suddenly develops, when put to the test, a faculty of managing all these difficult little matters I have mentioned. While her comrades plod on at perhaps 7½ cents an hour, she walks up rapidly into 8½, 10, 11, 12, 13, 14, 15, 17½, and then 20 cts., perhaps, in a short space of time comparatively. There is something encouraging about this, my young friends; when a girl or boy begins to *catch* the spirit of promptness and accuracy, he usually improves fast. It may take him a good while to go from 9 cts. per hour to 10; but he will go from 11 to 12 and 12½ in a much quicker time; 14 and 15 come frequently in a few months. Pretty soon he goes up to 20, and then he becomes able to take charge of a room full of hands, and works at a salary, without being obliged to report time every day.

I suspect, my friends, it is not only clerks in the office who need what I have written above, but very likely it is boys and girls, and men and women in every department in life. "He that is faithful in few things shall be made ruler over many things;" and I have, contrary to my first intention, put this here in the journal for the benefit of all of you, as well as for the clerks in the office. Occasionally we have clerks who think I am foolish and notional, and that they have more wisdom than I. May be they are right about it; but I have learned by past experience, that I succeed when my helpers fall into my

ways of doing things; and when they do not, I do not get along. So if they prefer their own ways and plans with small pay, I suppose it is their privilege to do so.

Ninth Hint.—Be very careful when you make any arrangement with a customer touching his ledger account, that your letter goes to the book-keeper, that she may make a minute on his ledger account of what you agree to do. For instance, a man receives some section boxes, and through our fault they do not reach him until his honey season is over. He asks us if he shall return them or hold them subject to our order. I indicate with my pencil the latter course. The clerk accordingly writes him, "Hold the goods subject to our order," and sends it off, distributing the letter. In due time the book-keeper sends a dun for the account unpaid, and our friend gets very much displeased, decides that we know perfectly well what we told him, and are trying to "bulldoze" him. I have been obliged to give up in despair a good many times, in trying to get a clerk that would remember things like this. The man's ledger page is something *sacred*, if I may be permitted to use the word. You have no business doing any thing with it, without promptly giving him notice. You might lessen the amount of his indebtedness by giving rebate, and he would not be offended; but you have no business charging any thing to him, or making any sort of an entry on his account, without his permission and direction; and this brings us to the—

Tenth Hint.—If you take the liberty of sending something to a customer he did not order, or something costing more than the article he ordered, a full explanation must be made at the time you do so, and you must always add, "Subject to your approval;" or, "If we have not done right in deviating from your instructions, write us immediately, and we will make it right." In such cases I think it a good plan to inclose a postal card addressed to yourself, asking him to say at once on the inclosed card if the arrangement is satisfactory. Every little while wrangles and disagreements between supply-dealers and their customers are submitted to me, and a great part of the troubles come because the supply-dealer took liberties, if I may so express it, with the money that was intrusted to his care. I have had so much trouble in finding clerks that would attend to this matter that I have sometimes said inwardly, if not aloud, "Oh for a boy or girl that would recognize the rights of those who send their money to us!" A great many assent to it, and seem to understand it; but when the rush of business comes, and unless my eye is constantly on every little detail, they charge a customer more for a thing than he expected to pay, because the goods have advanced, or because he had an old price list to order from, and not one word of explanation is given; or they will send him something a little different from what he ordered, without, a word; whereas, had they just penciled, "The best we can do; if it does not suit, write," all would have been pleasant; for I have found, by years of experience, that the person thus appealed to will, nine times out of ten, put up with a lit-

tle inconvenience; whereas, had the matter been left without any explanation, he would have naturally concluded that we did not care whether we obeyed orders or not, so we got his money; and about all the ugliness there is in him would have been stirred up so as to come to the surface.

Eleventh Hint.—I do not know how it is with other employers; but I want clerks who will not be partial to me. I know it is very desirable to have clerks who will look out for their *employer's* interests; but, my friends, I would a thousand times rather have a clerk who would look out for God's interests. What I mean by that is, I want boys and girls, and men and women, who will strive to do right before God, instead of before me; who will try to keep the spirit of justice constantly before them, who, instead of trying to make all business count in my pocket, will rather hold up the idea, and keep it before them, "What is just and right and fair, and honestly due these friends of ours who are intrusting us with their money day after day, even though they be hundreds and thousands of miles away?" I am glad to see my employes interested in my welfare, but I do not want any clerk partial to my interests, and I do not want one whose judgment is warped because he feels friendly to me. A great many of the bitter, hard, unkind letters that have been written have been because some clerk lacked in judgment in this matter, or because his judgment was woefully warped. Sometimes I have said to myself, "We can not have this clear-sightedness and impartial judgment without age," and I have tried older people; but I found just about the same difficulty. Do you want to know about what I have concluded, my friends? I have concluded that there is nothing in this world but true Christianity, and a love for the Savior, that can put self and selfish interests out of the human heart. Now, if I pay Christians more than I do those who are not professors, please be just enough to me to recognize that I do it because they exhibit this trait, and not because of their *profession*.

Twelfth Hint.—Never quarrel with a customer. Never allow yourself to even think, much less say, "This man does not know what he *does* want." A man or a clerk who quarrels with a customer, quarrels with his bread and butter. Treat all customers, whether you meet them personally or whether you get a letter from them, as if you thanked them, and thank God for sending them. Treat them as something sacred, not as though it were their *money* you were after, and that was all you wanted of them. We are often accused of the above, and I am afraid, dear friends, we sometimes deserve it; but after studying the matter carefully I have decided it is not so much selfishness as it is a sort of shiftlessness and laziness. The trouble is, it is this old *half-heartedness* I have written about before. And now, my friend, I do not know whether you are a Christian or not; but if you are making a profession of religion, and that religion does not stir you up to energy and zeal in working earnestly, faithfully, and hard for your neighbors, when the neighbors bring busi-

ness to you, then your Christianity is not worth much. I have before spoken of the talk we have about *doing good*; but I tell you, it is a thousand times better to do your *duty* as it lies before you on your table or on your desk or in your store or on your farm. Do your duty; do it well, thoroughly, faithfully, and unselfishly, and you will probably do much more good than in starting out as a missionary, when it is not your duty to be a missionary.

Thirteenth Hint.—When an order comes to you that for some reason can not be filled at once, be sure you promptly notify the one giving the order, and let him know what to expect, as soon as possible. New hands have troubled more than I can tell you by being remiss in this one respect. For instance, a boy is sent half a mile to the hardware store for some bolts of a certain size. When the time comes to use them, several men are brought to a standstill for want of the bolts. After considerable trouble the boy is found.

"John, where are those bolts you were sent for?"

"Why, they hadn't got any of that size."

"Then why did you not come to me at once, and say so?"

"Why, as they hadn't got any, I didn't suppose there was any use of saying any thing more about it."

"What is the nearest they had to the size you did want?"

"Why, I didn't ask them, and they didn't tell me."

Now, the boy was greatly at fault, and I should say the hardware man was at fault in not sending word what he had, larger or smaller, that might answer. It is not only boys, but men and women, that seem to be almost invariably guilty of this same way of doing business, until thus taught different after coming here. Obey orders to the best of your ability, and then notify the one giving the order the result at once; and *especially* should he be notified if you can not furnish what he asks for.

Fourteenth Hint.—Don't let any transaction slip out of your hands until it is completed. For instance, a new clerk once said that a man wanted to know the weight of our two-horse-power engines. I told her to write and ask the manufacturer. In a few days the answer came, and I gave it to the clerk. Pretty soon she asked me what she should do with it. "Why," said I, "write and tell him the weight of the engine, of course."

"But, I do not remember who it was."

"Did you not keep his letter or his address?"

"No."

"What did you tell him?"

"I did not tell him any thing."

"Why, is it possible that you neither wrote him nor saved his letter nor kept his address, after making such an inquiry as you did?"

"I did just as you told me to do."

You may smile, friends; but I have known older people of both sexes to be guilty of this same thing over and over, until they had been taught that they must keep the

address of such inquirers, in the computation-book, until the answer came. May be we lost the sale of a steam-engine by this little piece of thoughtlessness.

Fifteenth Hint.—Now, friends, in all the foregoing I have said nothing about lazy clerks. It is a fact, that there are some people who seem to expect they are going to get on in the world by lolling about in a lazy sort of way, gazing abstractedly out of the window, or marking idly with their pen, yawning and wishing it were dinner-time, etc. If you are working for a business man who expects to make a success of it, he will probably get you out of the way the first opportunity, if you are one of that sort of people. In fact, he can not very well do otherwise; and I am sorry to say, that when a person has got into a habit of loafing a great part of his time, so far as my experience goes he rarely gets out of it. One who will accept wages when he is conscious that he has idled a great part of the day is a good way down, on the road to the poorhouse. Sometimes when business is dull, and there is not very much to do, we find clerks who will try to spin out their work, as it were, to make a piece of work that they could do in a couple of hours, if they set about it with energy and zeal, last half a day or more. It is positively awful, to see to what perfection some people have brought this knack of being able to put on the appearance of being busy a long while on some little job. I have sometimes thought that one might almost as well take money out of the money-drawer of his employer, as to manage in this way. "Do with thy might whatsoever thy hand findeth to do;" and if you get all the work done up, tell your employer so. Then if he has nothing further for you to do, I think it would be money in your pocket to tell him you are going home, or take a holiday until he has some work to do. If you are a valuable hand, and he does not like to have you away, he will pretty soon find something for you to do. If you are not a valuable hand, set to work to make yourself so. This, of course, refers mostly to hands who work by the hour. A very common way of curing laziness is to set those who are addicted to it at work by the piece. But where one has become addicted to this habit of shirking duties, it is pretty hard curing him by setting him at work on piece-work. One who will cheat in regard to the amount of work he does will cheat in quality or cheat in count. Some honest clerk will have to waste his time in watching him; and my experience is, that the dishonest one eventually beats in the end. There is no other way to do, in the great majority of cases, than to dismiss him to annoy somebody else; and by and by he settles down and down, and eventually the county infirmary takes charge of him. This is a sad kind of picture, I know; but I hope you will take warning from it before you are old, and before your habits are fixed.

If you want to make progress in bettering your wages, when you work, work; and when you don't work, don't work. Either go ahead or stop altogether. Many times one doesn't feel like work. Now, if you are anxious to get up in the way I have been

telling you, at such times I would stop altogether, or else explain to your employer that you don't feel able to do your accustomed work, but that, if he wishes, you will stay and look after things as well as you can, at reduced wages. Very likely he will tell you, if you are much needed, to go on and do as well as you can, and it will be all right about the wages. This I know, he will thank you in his heart, if he does not say so. I recommend these explanations, because without them appearances might count against you; and in all this, dear friends, we want to accept the Bible maxim, and shun every appearance of evil.

Sixteenth Hint.—Be careful how you make free with the property of the establishment, without permission. Sometimes we get a new hand who straightway helps himself to matches, soap, towels, etc., without asking anybody. After awhile he goes into the store and takes tin cups and tin pails and the like, and always leaves them where he last used them—out in the lots, perhaps.

When the weather gets severely cold I often find thermometers hung up on the outside of the different parts of the building. These are put out, doubtless, to register the temperature. There they hang until I see them and put them back in their places, or until they are spoiled by rust and exposure. All these things might have been well enough had permission been granted to use them in this way; but where many hands are employed, the one who makes himself free in this way, or is guilty of such liberties, is out of a job speedily. Make it a point to get permission before borrowing or using another person's property.

Now, friends, in these remarks I may have erred in judgment, and may be there are other sides to many of the questions. But most of you have wanted to know how you can improve your daily wages. With the experience of years before me, I have tried to tell you as well as I can how you may help yourself, and help those you are working for, at one and the same time.

BEE CULTURE IN CUBA.

"IT IS NOT ALL GOLD THAT GLITTERS."

FRIEND ROOT: The above is true of Cuba; though a kind Providence has smiled upon this country in more ways than one, yet it has its dark side, a side that is bleak and gloomy, amid the glare of a noonday tropical sun. How can this be? You shall know.

A little more than one year ago we landed here with 100 colonies of bees; owing to circumstances that we could not control, Christmas found us with only 24 of the 100 colonies left. The 9th of January our first island-bred queen began to lay; from that time until the 11th of April, honey came in rapidly; and as increase was the end desired, all energies and means available were devoted to accomplish our purpose, and June 30 found us with 520 colonies. But, alas! "vaulting ambition had o'erleaped itself," and our increase was stopped only upon the eve of a four-months' dearth of honey (I see the smile that covers your face now), and I repeat the old adage: "Those laugh heartiest who laugh last." We had our laugh when prosperity smiled and kept smiling

upon us; but the day came, when, beneath a tropical noonday sun, the sharp shrill sound of the robber was all we heard. "Devastation and destruction" stalked abroad under this noonday sun, laying waste the hopes that we had stood upon for the last six months.

After the robber, came the moth; and with 520 colonies, all weak, and no honey coming in from the fields, to carry them through to the first of November was no small task. You ask, why did we make such an unheard-of increase? First, increase was what we wanted, and, urged on by the reports of native bee-keepers, that in August there was a good honey-flow, and in September the fall flowers began to bloom, we thought we could not well go wrong, and that there was really no limit to what bees would do in Cuba.

But, this has been our first year, and experience has taught us a lesson that has come to stay. The honey-flow in August did not come; September flowers failed to yield honey; October passed, and still the robber sought that which was not his own. But with the advent of November, the royal palm came to the relief of the hungry millions, and peace and plenty took the place of discontent, dishonesty, and death. We are on the road to prosperity now, but with many hives that are empty; every day brings us good cheer, and more of it. But, friend Root, this experience we had to have; no one could tell us about it, for they did not know this is the only apiary run upon the improved plan. What bees are kept are kept in log gums, and what do the keepers know about the honey-flow? They say they *think* that such and such is the case, but they have not the means of knowing the condition of their bees, or the amount of honey coming in, only when in the winter the bees get their rudely built hives full, and build comb upon the outside, then they know that honey is coming in fast, and there their knowledge of bee-keeping ends.

There are more things to learn about modern bee-keeping in Cuba, than to be able to tell exactly when the flow and when the dearth of honey comes. Here, as you know, the best surplus season comes in the winter, and it is winter with the bees. Although it is warm, plenty of flowers and honey, the nature of the bee is *not* materially changed; the queens lay about one-half what they do in the spring months, either here or in the North; they make no preparations for swarming, they seal up every air-hole on the top of the frames, just as in the North, and all their calculations seem to point in the direction of a season of rest and a winter's nap; but the winter, with all the severity of the North, does not come (yet it is cold here, quite chilly, but it does not freeze); the sun shines warm in the middle of the day, the flowers bloom, and, instead of "hibernating," the bees gather honey. But I think it is unnatural, and here comes in *one* of the great difficulties in Cuban bee-keeping; that is, in getting your colonies in proper condition to store honey at this unnatural time of the year. They are cross, they are *mad*; they don't want to be bothered; they want to be let alone; they want to sleep; they want to hibernate. They are apt to supersede their queens if you bother them, and every thing goes to show the close observer, that gathering honey and breeding in the winter is not as nature has designed it for the honey-bee. Bee-keeping in Cuba has many *ifs* and *ands* to it, yet I do not say that it will not eventually be a success; but, one thing is sure;

we have much to learn about winter management, and controverting the nature of the bee to our wants. Last spring we would not have given a big orange to have any one insure success; but, "where ignorance is bliss, it were folly to be wise."

November 20, 1884.

A. W. OSBURN.

JUST ALIVE, BUT DIED.

SENDING QUEENS ALIVE TO NEW ZEALAND.

ON page 797 of GLEANINGS for 1884, I told you that, "Early this fall I started a queen for New Zealand in the mails," but that it had not been heard from since it arrived at San Francisco, Cal. On the 11th of this month I received the following letter:

Mr. G. M. Doolittle:—The following will give you an idea of how the queen and bees arrived, which you mailed me Aug. 20th. Queen and bees came to hand on the 23d of Sept., at 3 o'clock p. m. All the workers were dead, and the queen gave the last kick when being taken out of the cage. I tried hard to revive her, but to no purpose. The cage contained stores enough to last another week. All the bees looked clean and bright, including the queen. I think the cold was the trouble. If you are agreeable, I will try next season one or two shipments, but one or two months later. Thanks for trouble you have taken. My bees are in good trim, and the clover is beginning to open plentifully. Hoping you have had a good season, I remain yours truly,
Normanby, N. Z., Nov. 8, 1884. G. W. EPPING.

By the above it will be seen that I only succeeded in getting a queen barely alive from Borodino, N. Y., to New Zealand, but my friend seems to think that it was the cold there which caused them to die. Quite probable he is correct regarding the queen, but I think that the worker-bees could not have lived to reach there alive, even had the weather been ever so favorable, for this reason: Bees younger than 5 or 6 days old are wholly unsuitable for sending in the mail; for bees younger than this do not fly from the hive under ordinary circumstances to empty the intestines of the pollen excrement they contain from the food they consumed while in the larval state; hence if such bees are shipped they will generally have the bee-diarrhœa, and fault themselves and the cage, causing the whole to die within a short time. Thus six days of the bees' life is passed away before it starts on the journey. As the average life of the worker bee in the working season is not over 40 days (none living, under the most favorable conditions, to exceed 45 days, as I have several times proven), it will be seen there can be little prospect of a worker, caged at 6 days old, living more than 34 days more. These bees were sent to friend Epping were caged at 11 o'clock A. M., on the 19th day of Aug.; and as he says they arrived there at 3 p. m. Sept. 23, it will be seen they were caged 35 days and 4 hours, or one day and 4 hours longer than we could expect them to live had they had their liberty, while life, of necessity, must wear out faster during the uneasiness of confinement. As these bees were sent by registered mail, I had a chance to know how long they were going across the United States to San Francisco, Cal., which proved to be in this case nine days. Now, if I lived in California I believe I could mail worker-bees successfully to New Zealand, as that 9 days would reduce the 35 days down to 26, which time could be endured by bees, even in confinement.

Perhaps some would like to know how I prepared these bees for shipment, so that they can try shipping long distances. I am a firm believer that the

day is coming when all queens will be sent by mail where the journey does not require more than 26 to 28 days to accomplish it; and the more trials there are the sooner will the result be accomplished. The cage and candy were made the same as was described by me on page 509, GLEANINGS for 1883, where I wrote relative to the queen I sent to Scotland. In addition to this I took a piece of clean old tough comb and fitted it securely in the middle of the two large holes, so fastening it that the bees could go over the top of it and have free access to both sides, where the cells were. In fact, the bees had a hive with one comb in the center, and plenty of food in the ends. My object in putting the piece of comb in was, so they could carry this honey from the "Good" candy and store it in the comb if they wished to, thus keeping them more contented, and make it seem more like home to them. I did not know that they would do this for certain until the next morning, when I was convinced they did by finding five times the pulverized sugar under the cage I had seen before under any cage left over night, and also by seeing liquid glistening in one or two of the cells which I could just peer into through the wire cloth. I am sorry friend E. did not tell me whether or not there was any liquid honey in the comb when it arrived. Those last kicks of the queen in New Zealand give me faith, and I shall make further trial next Sept. and Oct., in sending one the 25th of Sept. and one Oct. 15, should Providence spare my life, and friend E. still advises me to do so.

On page 820, Dec. No., I find these words: "It just now occurs to me that friend Doolittle's remarks about the sugar in the Good candy being of no value, will need a little qualifying when we talk about wintering bees on candy from sugar and nothing else." Now, friend Root, it almost seems as if you did not really want to understand, sometimes. Won't you please read my article on page 797 again, and see if it is not already qualified regarding wintering? In fact, the sugar is sometimes used by the bees in very cloudy, misty weather in the summer, in the cages, but never in dry summer weather; and when given to full colonies, the sugar is used in the summer only after it is moistened by the dew at the entrance, as friend Fradenburg tells us on page 27, 1884; at least, this is my experience.

G. M. DOOLITTLE.

Borodino, N. Y., Dec. 15, 1884.

I confess, friend D., that I had not gone over your article on page 797 when I wrote what I did, and I did not remember that you used the expression "warm weather." If you mean by not wanting to understand, that I am not willing to admit that bees can not eat dry candy in warm weather, I think I shall have to plead guilty. When I first recommended giving bees frames of candy instead of liquid food, our experiments were all made during severe droughts in August and September, and I built up nuclei, and fed them for weeks on nothing but hard candy poured into wired frames. On one occasion our apiarist left a wheelbarrow full of hives containing such frames of candy. It was in the middle of the day, and a very dry, hot day too; but in the course of an hour or two we had about as lively a time with robbing as you often see. In the back numbers of GLEANINGS I gave some experiments with dry coffee sugar. When sugar

was dried in the sun so as to be quite dry, it took the bees so long to manage it they worked on it almost as they worked on natural stores; but a little sprinkle of water would start robbing at once. Bake some sugar in the oven, if you choose, until it is as dry as you can make it. Then put it in the sun in the middle of the day, in a time of drought, when bees are crazy for any thing sweet, and they will take it up and use it at a pretty fair rate. In our back volumes this process is described for making bee candy direct from sugar, without any boiling, and I used it largely in *hot dry weather*. Very likely they bring water to moisten it, for this, of course, I can not dispute. If a jar of water, with a cloth over the mouth, be inverted over the candy they will take it much more rapidly. — It seems to me we have had several experiments, showing that bees during confinement, as in winter, may live ninety days or more. The little cages of bees we get from Italy, I think have sometimes been as much as six weeks on the way. May be they will not live more than 35 days when confined in the mails; but I should hardly be inclined to set the limit there, because worker-bees do not ordinarily live longer. I am glad to hear of even so much success, for it is a good deal better than we have accomplished ourselves in mailing queens.

ALLEY'S DRONE-TRAP.

A REPORT NOT VERY FAVORABLE.

IN the bill for goods last April I requested 24 queen and drone traps, as advertised. I supposed that you had plenty on hand. In your bill you have charged me with 12; but by some mistake there was but one trap sent. As matters have turned out with me, the disappointment amounts to but little. I saved about 20 swarms of blacks and Italians, and have not a single hybrid in either stock. I set the trap before a stand of bees; they could pass in and out very well when so minded; but about a third of them, after making a trial, became united, and went to other stands, and in less than a minute, got up a flight. After making three or four such trials I laid aside the trap.

SELLING, HANDLING, AND SHIPPING HONEY.

Bees in this section gathered honey the fore part of the season briskly; but after the first of August they made no surplus. Mine took the swarming fever just at the beginning of basswood bloom, which was over by the first of August, so I do not consider myself as an apiarist in running bees for money. I think it unnecessary to make a report of loss and gain. I will say, that I made about 2000 lbs. of section honey, about a third of which is not fit for market, owing to not being filled out and sealed over. Bug juice has not yet made its appearance in this country. There were some 30,000 visitors at the White Sulphur Springs, near Waynesville, last summer, many of whom came to see the bees and honey. The most of the honey that I sold was to them for samples to take home. Some bought a single box, some half a dozen, some a dozen, and some a whole case of 48 boxes. The ladies were so highly pleased with the honey and apiary they give it the name of Honey Dale. I have 15 cases ready packed for shipping, but the way they handle things on railroads, I am deterred from offering to ship.

unless I could go with the goods and handle them myself. Fortunately I am not needing the money, and may be able to sell at home next summer.

With the exception of section boxes, I have bee-furniture on hand, ready to meet the seasonable demands of another summer. My Italians have not had a chance to show their honey-gathering qualities, from the fact that I have kept down by making artificial swarms, and the latter part of the season we had ten weeks without a single shower of rain; though the landscape was blooming with golden-rod and asters, they furnished but little honey.

I have in all, 94 or 95 stands, nicely packed for winter, on their summer stands. W. FRANCES.
Waynesville, N. C., Dec., 1884.

Friend F., we sent you one drone-trap, and it was a clerical error in charging you for more than one. I have had some fears that the drone-traps might induce bees to go into the wrong hives—especially Italian bees, for in the busy season they often seem to think it does not matter much what hive they go into to unload their stores. Setting the hives further apart might partially remedy this. Have others had any like experience?

SOMETHING FROM OUR OLD FRIEND GALLUP.

CALIFORNIA THE PLACE FOR WIDE-AWAKE, ENTERPRISING BEE-KEEPERS.

I WISH to describe the success of one of our beekeepers here as nearly as I can, for the benefit of your readers. He commenced a few years ago a poor man. He took up a government claim of 160 acres. He now has a small stock of cattle, and during the winter season he sells on an average 50 dollars' worth of eggs and butter per month; raises quite a quantity of fruit, a nice vegetable garden which produces vegetables the entire year. His cattle obtain their living, and keep fat and thriving on the natural feed, without any care, the entire year. There has never been a season that he has not made some surplus honey since he commenced, and this season he has made 80,000 lbs., or 40 tons, as we reckon here. He has money at interest, and is now well fixed financially, so that he can hold his honey until the price suits. He has 10 tons of last year's honey on hand—in all 100,000 lbs. He hired one hand this season for 3 months at \$25.00 per month. He keeps his own team, and does his own teaming. With the exception of the hired man he has done every thing himself, with some help from his excellent wife and children. He has, or had in the spring, 270 stands of bees.

The price of honey here now is 4½ to 5 cts. wholesale. Now, this man has demonstrated that bee-keeping is a success when properly managed, even in a poor season; as, since he got his stock of bees up to 100, he has made honey every season. I think the lowest was 6 tons, and from that to 8 tons; but when he had the small yields he had a good price. His cash out is 80 cts. per case of 120 lbs.

There is no loss of bees in wintering, and no care whatever from September to February. He always keeps his bees in good condition, and leaves their hives full of honey at the end of the extracting season.

I might tell you of another man who commenced about the same time within six miles, and is now some \$600 in debt, and this season made 8 tons of honey, sold it for 4½ cts., keeps three dogs, no stock of any kind, because it won't pay to bother with

them, and still he has an excellent range. Cows are worth only from 80 to 100 dollars each here; beef, 12½ cts. live weight; eggs, 36 cts. per dozen; hogs, 5 cts. live weight, and in half a day he could fence across the canyon and then turn in calves at from 7 to 10 dollars per head, and let them grow to cows or beef without any further trouble. Such is life in California. This last man cries hard times; has been in the country ten years, and has never yet set out a tree of any description, nor a grapevine; buys all of his vegetables, etc., and still he is quite an energetic man; for if he can, by climbing over the mountains, and carrying a heavy rifle, succeed in killing a fat deer once in a while, it is a great success. E. GALLUP.

Santa Ana, Cal., Dec. 8, 1884.

Friend G., we have been very much interested indeed in getting a word from you once more. I was a little disappointed when I got to the end of your story, to find out that the man who had done so well was not named E. Gallup; and then I thought may be that last man was going to turn out to be you; but I soon saw I was mistaken there. Now let us know what you are doing, old friend. Why don't you have a big bee-ranch, and give us something in every number, as you used to do in the old *A. B. J.*? Why, friend Doolittle quotes you now every little while, and yet you are letting all the skill and wisdom you possess in regard to bees, waste its sweetness on the away-off California desert air, are you not? Is the doctoring business so good out there that you can not have just a few bees, old friend?

TRANSFERRING.

SOME HINTS FROM FRIEND MASON.

THE tools required to do this remarkable job are a hand-saw to saw off the cross-sticks, a hammer, a cold-chisel, and a common case-knife. We also want a ball of linen twine and some woolen cloth. We now take our new hive, supplied with three frames of empty combs or foundation. Sometimes, when convenient, we use one frame of brood drawn from some other hive, but this is not essential.

We now go to the stand of the colony we wish to operate upon, smoke the bees, saw off the cross-sticks, and with the hammer and chisel cut the nails so as to get off one side of the hive. We now place some woolen cloth in a box, and cut out the combs with the case-knife, brushing the bees all directly into the new hive, which should sit now on the stand of the old one. As the combs are cut out and the bees are brushed off, a piece of the cloth should be laid between each comb; the old hive should be carried away, and the box of brood-combs carried to the house, put in a warm room, if cold, or into the shop, and then transferred in to the frames. For fastening in combs I find linen twine far the best. Cut off four strings, two long enough to go around the frame endwise, and two widthwise; lay down these strings, and on top of them the frame. Fit in the comb, and tie it in with these strings, then bring the frame to an upright position; and if any more string is wanted to secure it, use it. When the combs are all fastened in, carry them to the colony, and shake the bees from the frames left for them to cluster on, and give them their combs. In

this way you need keep the combs exposed but a very few moments, and then you can transfer in your room without bother from the bees. I have found this the best plan, among all I have tried.

Mechanic Falls, Me., Dec. 4, 1884. J. B. MASON.

THE SCIENTIFIC BEE KEEPER.

THE MAN WHO KNEW ALL ABOUT BEES.

"YES," said he, "bee-keeping is now reduced to a science; and all that we have to do is to make this science a study, just as we study surveying or civil engineering, and we are bound to succeed. I know all about bees; I used to keep them years ago, and I've read Quinby's bee-book, and to me bee-keeping is a science—no more, no less; I say, give a man bees, and give him also the science of bee-keeping, and he will make money. Now, in my experience—" But I waited to hear no more; I was cooking dinner, and he was one of the folks who will neither come in nor go away, but will keep one standing on tenter-hooks in the door all day, and he was so deaf that all my words were lost on him. He had bought a colony of bees of me a few days before, and he had come now to see about them.

That evening about dark he came for them. The day had been hot, and the portico was full of bees. I told him to wait till morning. "No," said he, "I'll take them now; I'm not afraid of bees; I'll let every bee in that hive sting me, if any one will pay me for the bees; all that a man needs is to understand the science of—" He had his sheet spread down by this time, and he took hold of the hive, one hand at the back, the other at the top of the portico in front, when a handful of bees seemed to sting him all at once. He dropped the hive, executed a war-dance, and yelled "Jerusha! Jerusha!"

He wore linen pants, and the bees climbed up on the inside, and stung him right and left; and at every spear-thrust he jumped clear off the ground, and yelled "Jerusha!"

I suppose "Jerusha" is his patron saint, from the way he called on her in his affliction. When the bees got to putting in their best licks he did not have time for the whole word, so he said "Je—" (with a slap and jump) for one sting, "—ru—" (slap-jump) for another, and "—sha" (jump-slap) for the third; then he seemed to lose all account of syllables, and he danced a Highland fling, and uttered a perfect chorus of "Jerushas." Our whole family were gathered around, and they held their sides, and laughed, while the boys rolled on the grass, and screamed, and called for some one to fan them and rock them.

Well, they tied the bees up in the sheet, swung them on a pole, and carried them home; and next day they sent for me about ten o'clock, to come there and cover up those bees. I found the hive open, the cover lying some ten feet away, and no scientific bee-keeper in sight; all the family had business in the lower pasture, or the cow-lot; and when I got in speaking distance of them they said that my scientific bee-keeper was in the cellar, with the door locked, so that none of the rest could get in, and they were obliged to take to the woods. I straightened the frames, put on the covers, and left them in the care of the "scientific bee-keeper" who had read Quinby. MAHALA B. CRADDOCK.

Vermont, Ill.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

BEES AND—SEED CORN.

I COMMENCED in the spring with one strong and one very weak colony. The weak swarm dwindled down to a mere handful; but I saved them by giving them frames of hatching brood from the strong swarm. The strong swarm threw off one swarm the 15th of June, which was all the increase I had. I took from the three, 100 lbs. of comb honey in one-pound sections, which I consider doing exceedingly well for so poor a season as we had here this summer. Both apple-tree and basswood blossoms were cut short by severe frosts.

I have a little matter in which I am undecided how to act. Last spring I sold some seed corn to a friend of mine. So little of it grew when planted, that the crop was a failure. The one I sold it to claims the seed was poor. I claim it was good, and the cause of the failure was due to the seed being destroyed by worms. I think I have very good reason for so claiming, from the fact that I sold seed corn to two other parties, both of which were well satisfied, and obtained good crops from it. Now the question with me is, Should I or should I not take pay for the corn I sold to the one that had the failure? Of course, the friend suffered quite a loss by the crop being a failure. But for all that, it seems to me I should not lose the price of my seed corn, it being successfully grown by two other parties.

B. H. BRADLEY.

Eddyville, N. Y., Nov. 28, 1881.

Friend B., this matter of seeds has been a good deal discussed, and there is a difference of opinion in regard to how far a seedsman's responsibility should extend. A few years ago a decision was made against a seedsman, because the crop did not grow, and you may have noticed that most of our prominent seedsman straightway put a note on their seed-packages, declining all responsibility. Where proof has been shown us that the seeds we send out did not grow, we have refunded the value of the seeds, or furnished more. But inasmuch as there is such a diversity of causes that may produce a failure of the crop, it does not seem to me as if the one who sells the seed should be held responsible, further than this. If two other parties obtained good crops from the same seed, it would seem as if this were evidence enough; but very likely your friend may have something to say on the other side. I think you ought to have pay for your corn, as you state it.

LEAVING THE ENTRANCE WIDE OPEN IN THE WINTER TIME.

IN GLEANINGS OF Dec. 1, page 820, you say of bees wintered outdoors, "They should by all means have the entrance so they can get out and in when the weather is suitable." Now, I know of instances where at sunshiny days in spring, bees would come out in large numbers; and if there were snow on the ground they would fall on it, and the owner would lose most of his bees. What do you think of it?

F. A. LAVOIE.

Montreal, Dec. 3, 1884.

I know it, friend L.; but after having tried shutting them up, or putting a wide

board in front of the hive to shade the entrance, and all such arrangements, for many years, I have decided that I would let them fly whenever they want to. If bees are in good health, and have not been fussed or "tinkered" with, I do not think they will lose enough at such times as you mention, to do any harm; any way, I am satisfied the harm done by fastening bees in at such times is greater than to let them "slide." I know Doolittle and some others have recommended closing the entrance of the hives at certain times in winter, and then opening them again when the weather demanded it. But our bees in chaff hives have wintered better with the entrance open at full width all winter, than in any other way. This matter we have tested by many experiments.

HOW TO PUT SIMPLICITY HIVES TOGETHER RIGHT.

I received my ten Simplicity bee-hives ordered from you through my friend N. H. Burns. So far they seem to be all right, as I have not put them all up yet. Such a time as I did have trying to understand the things and get them put up in good shape! I at last called in the counsel of my good wife, and every thing joined like a charm. I commenced four years ago with one hive. I now have eight strong swarms in common hives; have given them very little attention, and had a supply of honey, besides disposing of a few hives, and now I wish to commence at the first with Simplicity hives and A B C book, and give my bees careful attention. I have a fine ranch for bees as well as cattle, and hope to be equally successful. Unless a very dry season, we have a great variety of flowers, and bloom of trees. Cat-claw and mesquite blossoms make the clearest and best honey of all.

P. A. GRAHAM.

Albany, Shack. Co., Tex., Dec. 9, 1884.

Friend G., that is what I call good sense and wisdom. If many of us, when in trouble, practiced the plan given by friend G., I think many of our troubles would disappear like frost before the rising sun. We have the words of sacred Scripture for it: "It is not good that the man should be alone; I will make a helpmeet for him." When you asked your wife to help you out of trouble, you were fulfilling the command of Scripture; and if she is not already conversant with your work, and knows how to work intelligently, the fault is yours that you have not made her a partner in every thing that interests you.

WINTER FEEDING.

A most interesting article on sugar syrup for bees appears in the issue of Nov. 15. Not only is the subject fully discussed by Mr. Doolittle, but your own extended remarks on the same are excellent. The one point, however, on which some of your numerous readers may, like myself, desire yet more light is the mode propounded for candy feeding, and the possibility of successfully operating any day in the year. Assuredly this, if so, goes far to solve the problem of food supply. We need not be alarmed on finding hives light, in going into winter quarters, or having neglected to feed in time, or in finding, during winter, supplies run low. Simply put on a few cakes of candy, and all is well. No more fussing with feeders. The point is, will this disturbance of putting on the congenial supply, and excitement

at finding such abundant and suitable stores, not unduly stimulate, both rousing to activity or uneasiness, and to early brood-raising, then likely resulting in spring dwindling?

This facility for feeding, any day in the year, looks decidedly like a pretty long stride in advance, if it can be as readily managed as indicated. There is yet another point that may need to be put a little more plainly. You speak of confectioners' sugar. Confectioners use various grades. The standard granulated is mostly regarded as the proper quality for feed-syrup; but for this mixing with honey into the consistency of dough, a softer sort would seem more suitable, both for sticking together and for the bees licking or chewing the more readily. These gritty grains must give much labor to nibble off; besides, they do sometimes carry out crystallized pieces as unmanageable. Might not a good quality of soft sugar be less objectionable? Then, what about water for moistening? Wouldn't a little wide-mouthed bottle, with a piece of cloth over its neck in the midst of the candy lump, be very convenient to wet their tongues occasionally? I mean to experiment a little in the given plan, and shall also hope to hear of others trying and succeeding on the line of this honey-dough idea.

Toronto, Dec., 1884.

JACOB SPENCER.

Friend S., this matter of putting a bottle of water near the lumps of candy was, as you may remember, discussed and experimented on most thoroughly some two or three years ago. As a rule, I do not believe it advisable to give bees water until you wish them to commence brood-rearing in the spring. The candy and sugar laid on the frames will not, I think, excite the bees to undue activity in winter.

WHAT TO DO WHEN A MAN HAS A WIFE AND A BOY, AND IS IN DEBT.

I bought 20 acres of land, and built on it. Our house is small, 14x28 feet, but we make out very well. Our family is also small. I have a wife and boy and baby, 6 weeks old. We call her Chloe Mabel. How is that for high? I wish you would tell me how I can build the cheapest for my bees, and arrange the yard for them. I have a nice east hill-side for my bees and poultry-yard that will do the business I shall carry on, if I don't make a fizzle of it. I am considerably in debt, but will do my best to get out.

A. B. HOWER.

Mexico, Ind., Dec. 9, 1884.

Well, friend H., the first thing I would do if I were you, I would make up my mind that I would get in debt no further. As for the bees and poultry, if I could not scoop out some place in that eastern side-hill for them, without getting in debt any more, I would let them stay outdoors till spring. Probably the best place for the bees will be outdoors, protected from the wind, if you can manage that. If you can make a cave in the side-hill for the poultry, they ought to give you quite a lift by way of eggs now while they are high. If you had some old sash, so as to let in the sun and keep out the cold, it will do very well. Sometimes people in straitened circumstances say they can not get along without getting in debt more. In almost every case they can get along; and when they get used to it they feel all the better for it. Stop the accumulation of debt,

if it takes a leg to do it; and when you have got that mastered, you will find the matter of managing to pay a little every week or month is comparatively easy. Just make up your mind it has got to be done, you and that good wife of yours, and then put in and make things fly around for the sake of Chloe Mabel and her brother, if for nothing more.

FROM 5 TO 14, AND 30 LBS. OF HONEY.

The past season here was extremely poor. No rain between May 25 and July 25; then we got 1½ inches, then none till September 28; no good for bees. We wintered five last winter; no loss; took a little honey, 30 lbs., for a sweet lick, but fed 40 lbs. granulated-sugar syrup; have 14 in a house.

What personal experience have you had with the Carniolan bee? also the Syrian? I intend to try to teach our bees to work on red clover. Spray the bloom with water well sweetened with honey.

J. D. BEACH.

Coal Run, Wash. Co., O., Dec. 17, 1884.

Friend B., Mr. Benton has our order for some Carniolan queens, but we have had no experience with them. They come highly recommended, but so did the Syrian and Holy-Land bees.—You need not go to the pains of teaching your bees to work on red clover. Whenever there is honey in red clover they can reach, they will find it—you can rest assured of that. It occasionally happens, or, rather, we have occasionally a season, when this occurs, and very likely some varieties of red clover are more apt to have this profuse secretion of honey than others. The matter needs investigation and development.

THIEVES IN THE APIARY, ETC.

I have been in the bee business over ten years, beginning with one hive. My apiary numbers a little over 100 colonies. This is not a good honey section. White clover is just getting a start. The basswood did not amount to anything this year, and seldom does. The wind and rain in the fall spoiled that crop, consequently this has been a rather poor year. I increased over 50 per cent this year. During the past ten years I have learned much by experience. I have quite a number of little notions, etc., of my own, some of which may appear in GLEANINGS in the future. You express surprise in the last number, that any one should stoop so low as to destroy hives in order to get a little honey, which expression from a person of your age and observation is a surprise to me. The very meanest and most exaggerated thing that we can imagine, humanity will stoop to, and even lower. I am happy to say, however, that we have never lost any thing to speak of from honey-thieves. Some one entered the apiary three or four weeks ago and took off the covers from three hives, and laid them on the ground. I rather think they were looking for box honey, but they struck a "desert place" for that. The most mysterious thing to me is, why they did not put the covers back, and also why did they not take out some of the outside frames, which they could easily have done.

JOHN F. WHITMORE.

Anita, Iowa, Dec. 16, 1884.

Friend W., I think it a great deal better to have too good an opinion of humanity than too poor a one; and I insist still, that it is more ignorance than real badness of heart. Those who took the covers off your hives were looking for box honey. They did not

find any, and therefore they did no damage, more than to leave the covers off; and my opinion is, that it was more because they did not think any thing about it, than because they did it purposely. I once myself helped to eat honey that I knew was stolen from a minister's bee-hives, and I was a Sunday-school boy at the time. Had some good kind Christian friend taken me in hand just about that time, and presented to me the full aspect of the case in all its bearings, I believe I should have repented with tears, and perhaps gone to the minister and made reparation to the fullest extent in my power, and I believe it is much the same with those who went to your hives. It is lack of teaching, and, may be, lack of God-fearing teachers. The harvest is great, but the laborers are few.

FRIEND VANDRUFF'S UNCONDITIONAL SURRENDER.

My report this season will be small. I began the season with 18 colonies, with the majority of them weak. I doubled my number by feeding over a barrel of sugar. I took less than 200 lbs. of honey. The spring bloom was good; never saw it better, and the bees got a fair start, and I never saw a better show for white clover. The fields were fairly matted with it, and I expected a large yield of honey. There were plenty of bees, and a large increase of colonies. But, oh the dry season! Well, I almost got into Blasted Hopes. The white clover was just making a nice start, but it needed rain, and I was hoping for rain just in a day or two for a week or two; and seeing the clover all dying and drying up, and yet no rain, I had to make an unconditional surrender, and take off my section boxes, and make the best out of it I could. Yet I don't mean to give up; we don't often have such dry seasons; it is not the only pursuit that fails. I believe we bee-keepers can winter our bees with less expense and trouble than any farmer or stock-raiser can his stock. I now have 36 colonies prepared for winter, and I think they will all winter.

THE CARNIOLANS.

You wanted to hear from the Carniolans I got of Frank Benton. Well, the season was so dry I had a poor chance to give a fair trial. I did not get to try them in section boxes, but I believe they are very much inclined to swarm. They swarmed twice, as poor a season as it was for swarming. But a good season may make them all right. They are as quiet as any one could wish, yet I think albinos are as quiet. I have a colony of albinos I got last spring of S. Valentine & Son; they are beauties, and as quiet and gentle as kittens—that is, tame ones. They don't even scratch; likely they don't know how.

W. S. VANDRUFF.

Kirby, Pa., Dec. 10, 1884.

SUB-EARTH VENTILATION.

I shall probably send occasional subscriptions for GLEANINGS in future, as I am not only pleased with its excellence of practical information on apian subjects, but I am more especially pleased with its loftiness of moral tone. May God bless you in your editorial work, and aid you in keeping up the morals of the bee-keeping business.

I have devised a cheap house for wintering bees, which I think is as good as the more expensive ones. Admitting air through a drain, or any underground passage resembling a drain, is, it seems to me, consummate folly. You would not like to

have your bedroom filled with such air. My plan is to make the floor, walls, and ceilings, of hay, $\frac{3}{4}$ ft. in thickness. Outside of this is a wall of boards, and over it a roof. The wintering-house for this part of Canada must be cheap and warm.

T. HOWLAND.

Ormond, Ont., Can., Nov. 25, 1884.

Gently, my good friend H. If you have never used sub-earth ventilation, how do you know that the air that comes through the pipe is bad? In draining fields, the water that comes from our underdrains is as pure and sweet as any well or spring water, and the workmen often fix a place at the outlet to get a drink. Now, my opinion is that passing either air or water through the ground in no way injures it, either for breathing or drinking. In speaking of drains we often think of tubing put under ground for carrying off soap and water, and other slops from the kitchen. Of course, we do not want the air we breathe brought into the house in such a manner; but if it comes through a clean pipe, laid three feet or more under ground, where nothing gets into said pipe except the water that might percolate through the soil, I do not see how the air should be objectionable. The air in underground caves is, if I am correct, very pure, especially where there is good circulation, as there would be through our sub-earth pipe. Very likely hay would be good for walls for a wintering-house. With sub-earth ventilation, air is taken directly from outdoors, away off in the lots, perhaps, where there are no buildings nor smoke. This air simply passes through the underground pipe, and is in on way altered or changed in this passage, except to have its temperature raised to the temperature of the ground through which it passes. You suggest a caution which we thank you for; that is, our sub-earth ventilation-tubes must be so placed that no foul water from sink-drains can get into them. If it did, we might have typhoid fever or cholera right speedily.

DEATH OF ONE OF THE VETERANS.

W. W. Rowley, of Eaughalle, one of the largest bee-keepers in this part of the country, and one whom you have dealt with some, is dead; he died very suddenly at this place, when taking off some honey to market, to St. Paul.

HAVING NOTHING BUT YOUNG BEES IN THE SPRING.

There is a man in this neighborhood who winters his bees in a sawdust house (walls 14 inches thick). About the middle of the winter they commence breeding, and the old bees die off. He boasts of the amount of dead bees he carries out in spring, and says his bees are all young to begin work. He has had good success for several years.

I want that book on gardening, when I can get it and pay for it. We are trying to make ourselves "useless."

W. FULLER.

Woodville, Wis., Nov. 27, 1884.

We are very sorry to hear of the death of friend Rowley. His name has been for years a familiar one with us.—In regard to having all the old bees die off, I do not believe I should like that way, even if it does succeed well, for several seasons. I have seen them die off after the bees were set out of the cellar, at such a rate that the young ones turned in and followed suit also.

FRIEND HAMMON'S DIVISION-BOARD.

Herewith I send you the kind of division-board I have adopted for winter use. By "looking through the knot-holes" you will see a paper inside lining, then sawdust, that covered with paper, then the wood outside, then it is ready for use. I have put up 55 colonies of Italian bees, each hive put into a box with a space of three or four inches, and that filled with dry leaves. I use the Langstroth ten-frame hive. I have prepared them for winter this way, taken out the two outside frames, and substituted in their places the "sawdust" division-boards, and covered the frames with quilts my wife made by cutting up partly worn bed-blankets. The bees had a fine fly on the fifth inst., it being very warm.

Bristolville, O., Dec. 8, 1884. H. B. HAMMON.

I will explain to our readers, that this division-board is simply a common frame with thin sawed veneering nailed on each side. The veneering is such as is usually found on the back of picture-frames. This veneering extends beyond the ends of the frames so as to fill the hive, and also below the bottom-bar, so as to nearly if not quite strike the bottom-board. The device is hardly new; but the sheets of paper to put over the sawdust, and next to the board, are somewhat new. The board would be about as warm as a chaff-packed division-board, only thinner, and the expense would be considerably less.

RECIPE FOR HONEY-CAKE.

I saw something in GLEANINGS about honey-cake; and as I have been experimenting a little with honey I will send what we think a good recipe for honey-cake. Two cups honey, one cup sour cream, one-half teaspoonful of soda; flavor, mix quite soft. Some do not care for any flavoring, as the honey is sufficient. If you have not a better recipe you may publish this, as I know it to be good. This makes just a common every-day cake. Perhaps some may have a nicer one. We have GLEANINGS, and like it very much. I have put up all my fruit this season in honey, and have even made jellies with it.

MRS. L. M. HARDISON.

Santa Paula, Cal., Nov. 18, 1884.

MATERIAL FOR CAPPING BROOD-CELLS.

On page 804, Mr. A. A. Fradenburg's theory as to the material of which the caps to brood-cells is composed, and the manner in which it is obtained, is nearly as thin as the "pollen theory." I have seen all sorts of trash—sticks, sand, plaster, wire, paper, and any thing that happened to be in the way, fastened in the cappings, the bees' only object (seemingly) being to get a lid for the cells. They sometimes do very rough jobs of brood-capping when there is an abundance of other labor on hand during a heavy honey-flow. As to the bees "raking" a fibrous or lint substance from wood surfaces, if this is true in the brood-rearing season, when there is brood in 9 combs, and bees enough to cover only 6, I should expect to find nearly all the bees in a colony "raking hay," and, in accordance to bee nature, I should expect to find more of them on weatherworn basswood boards than on the front side of well-painted hives and pieces of glass which I keep leaning against the front sides of my hives.

I believe it has not been reported, that bees cap honey-cells with any thing short of wax, and we find the capping to some honey-cells that resemble that of brood-cells inasmuch as to defy distinction. And if we shut a colony in a glass box, allowing

them honey and water only, we find the capping of brood-cells pregressing as well, if not better, than before. I have seen new combs produced from basswood honey, that presented the appearance of a fibrous composition, but I remember that they were built by old bees, and at a time approaching a dearth of honey.

C. W. DAYTON, 114.

Bradford, Iowa, Dec. 4, 1884.

FEEDERS AND FEEDING—A CAUTION.

The hive of bees you expressed to me last June, was received on the 10th in good condition. The one you expressed to me in July, 1883, a fine big swarm, was led out on the 20th of June. Another young swarm was led out July 4. At the time of swarming, wet windy weather prevented the bees from working. I fed the young bees sugar syrup in tin cans, on their alighting-boards. This way of feeding started the old bees to robbing. The young bees would fight at their own hives, and would go to the old hives and fight there too. Their fighting lasted ten days; not one of them was beaten, but were all much reduced. The rest of the season, the bees in the old hive kept a standing army at the entrance of their hive, to keep the young bees from robbing them. I got no honey this season. I think they have plenty to bring them safe through the winter.

JOHN HAMSWORTH.

Sunny Meade, Assiniboia, N. W. T., Can.

Friend H., that is just about the way feeding works, if you are not careful. You just about express it when you say the old hives kept up a "standing army." Be careful about feeding.

WHAT TO DO WITH BEES THAT COME OUT AND DIE ON THE SNOW.

I should like to have one question answered through GLEANINGS, if you can give it room. Is there any way to prevent bees from coming out of their hives, and dying by the hundreds on the snow? Will it do any good to shade the hives?

E. D. BARTON.

East Hampton, Ct., Dec. 3, 1884.

Friend B., bees seldom if ever come out and die on the snow, unless something is the matter with them. It has been suggested, that sometimes they come out because the sun shines directly on a thin hive, and warms it up, when they would not come out if the hive were shaded. This may be so, but I am a little inclined to doubt it. However, I greatly prefer to have them in chaff-packed hives, not only to keep the sun from heating them up too quickly, but to keep the frost out as well. When bees have unwholesome stores, and are affected by dysentery, or some like disease, they come out and die on the snow in all kinds of weather, and I do not know that any thing can be done for them, unless it is to give them good honey in place of the bad, or, what is the same thing, sugar stores. A few bees will always come out, such as die of old age and other causes, and in a very powerful colony the number might be so great as to cause a novice to feel worried by it, when it is nothing more than what might be expected. A strong colony will probably throw out, say a handful of bees, after a cold spell of three or four weeks; and when these happen to be scattered about on the bright snow they give one the impression that the number is much greater than it actually is.

MORE LABELS WANTED.

The labels were received yesterday all right; accept my thanks for promptness. The pails are the nicest and cheapest I have ever had. I think you should get up a label to fit the pails. It is very necessary that the paper should go around the pails and lap, or they will peel off. I am doing very well; am averaging over 100 lbs. per colony each year, about one-half each of comb and extracted.

L. A. PENNOYER.

Winona, Minn., Dec. 25, 1884.

I know we need a nice lithograph label for each one of the nested pails we are selling; but to tell the truth, we have already so many different kinds of labels that a clerk has to be employed to look after them; and even then it is hard keeping track of what we have in stock, for we have made almost every thing that has been asked for in this line. Another thing, a lithograph label large enough to go around the four-quart pails will be a pretty expensive affair. We have Jones's labels that do very well for pint and quart pails, but none for the 2, 3, and 4 qt.; and as it costs about \$400 or \$500 to get out a nice lithograph label, as large as these we require, we should be obliged to buy them by the million, almost, to get our money back; that is, if we sold them at a reasonable price. Friend Jones monopolizes the matter so far, I believe, on his lithographic colored labels for honey-pails.

NOTES AND QUERIES.

LAST YEAR'S SECTIONS ON WHICH THE BEES HAVE MADE A START.

I HAVE 600 sections with full-size starters, that have been propolized. Will the bees use them again, or must I put fresh starters in? I got 116 sections with *some* honey in them—don't think they would weigh 75 lbs.

Elston, Mo., Dec. 6, 1884.

I. F. LONG, 5-17.

[Friend L., your sections containing *fdn.* partly built out are a great deal better than new ones. The same with those containing *some* honey. If any of it is capped over, uncap it before putting on the hive, and then they are just the thing to start the bees quickly.]

BEES, ETC., AT THE WORLD'S EXPOSITION.

Please add to the call for convention, that the *time* of exhibit of colonies of bees will only be during the *week of convocation*, and not as published in the Premium list.

J. P. H. BROWN.

Augusta, Ga., Dec. 12, 1884.

CISTERNS; A CRITICISM.

All should be interested in making cisterns, and in a pure supply of water. Putting the waste-pipe at the bottom, so the sediment will wash out, seems to be a taking idea with some. It is undoubtedly good, if true. I have not tried it practically, but should expect this waste-pipe to act as a siphon, and empty the cistern in case of an overflow. You can laugh all you want to, but it strikes me so, at first blush.

J. M. SHUCK.

Des Moines, Iowa, Dec. 1, 1884.

[Friend S., the overflow-pipe would act as a siphon were it air and water tight; but as this pipe is cemented only at the joints until it reaches the top of the ground, or a little further, there is no danger of its acting as a siphon, for plenty of air gets in at the highest point where the bend comes.]

CHAFF HIVES FOR WINTERING.

I have made 103 chaff hives this winter, and never will try to winter bees in this section any other way.

CLARK CHANDLER.

North Blandford, Mass., June 4, 1884.

REPORTS ENCOURAGING.

MY REPORT FOR 1884.

NUMBER of bees in spring; 116 stands, doubled back to 96 stands. Number now, 137 stands. Took 10,000 lbs. honey; 8625 extracted, 1525 lbs. comb. Honey all sold, extracted at 8 cts. at wholesale, comb 12½ and 13 cts. I had about 3 bbls. of "bug juice." It went with the rest; sold to cracker-factories at Cedar Rapids, Iowa. Shellsburg, Iowa.

ROBT. QUINN.

10 FRAMES AND 80 SECTIONS FILLED WITH BUCK-WHEAT HONEY IN ONLY 12 DAYS.

This has been a very good honey season with us; the spring was very backward, and our stocks dwindled till they became weak. I started with fifteen—seven in very good order, and eight weak ones. I had no swarms until the last of July, when we had two. The 5th of August we had five all come out at once, and alight in one place together, and I happened away from home that day, but they managed to get three of the five queens, and made three swarms of the five; but they were hives full instead of swarms, so I filled the hives full of frames and sections, 80 in each, and in 12 days one of those hives sent out a very large swarm. I happened away from home that day again, so the next day I thought I would give them some of the sections off the hive they came from, as I thought they would not need them on that hive, when, to my surprise, I found the whole 80 sections filled and ready to cap. They did not seem satisfied after they left the hive. They swarmed three days in succession, every time clustering, and we hived them until at last I returned about half of them to the old hive, and gave the other half to a couple of weak ones, and all was peace with them then. I suppose they swarmed for the want of room; but, why did they keep swarming? We increased to 21, which is the number we have now. We have taken off 1030 finished sections, and have quite a good many that were not finished. I never saw honey come in as it did in buckwheat-bloom; it would almost seem impossible that a swarm of bees could fill ten frames and 80 sections in 12 days, but that is the fact.

Accord, N. Y., Oct. 24, 1884.

WILLIAM PALEN.

FROM 3 TO 6, AND 300 LBS. OF COMB HONEY, AND NOT ENOUGH TO SUPPLY THE DEMAND, EVEN THEN.

This is my report for 1884: I had 3 hives of bees in the spring. I got 6 swarms of bees and 300 lbs. of comb honey from them. I sold 75 lbs. at 25 cts. a pound; the rest I sold at 12 cts. a pound, or 5 pounds for a dollar. I didn't have enough to supply the demand at that price. I sold the most of it in the shop where I work.

MARSHALL DARLING.

Waterbury, Conn., Dec. 1, 1884.

MY REPORT FOR 1884.

I commenced the season with 5 weak colonies; increased to 10 by natural and artificial swarming, all strong and well supplied with stores. I took about 60 one-pound sections, and extracted about

250 lbs., making 300 lbs. in all. Started with black bees in spring; bought 3 Italian queens, and made artificial swarms with them. I am aware that my report will look like small potatoes, and few in a hill, beside most of the reports from Texas, and I shall try hard to do better next year, although I think I have a poor location. We did not have any rain to do any good from June to October.

G. W. E. KELLEY.

Tanglewood, Lee Co., Texas, Dec. 22, 1884.

FROM 71 TO 175, AND 500 LBS OF HONEY.

I commenced the season with 71 colonies, half good, the rest below par, having sold most of my best colonies. I made 2500 lbs. of white-clover honey in one-pound sections, and 3000 lbs. of extracted basswood and white clover; comb honey all sold at 15 to 17 cts. per lb., extracted going off at 8 to 12 cts. I increased to 175 colonies reduced down to 140 by uniting all colonies with old queens to colonies with young prolific queens. I put 130 colonies into cellar Nov. 24, weather being three degrees below zero; chaff packed ten colonies on summer stands.

WM. ADDENBROOKE.

North Prairie, Wis., Dec. 8, 1884.

It seems to me, friend A., you ought to be satisfied, and it seems to me, too, that Wisconsin does "pan out" pretty well this generally speaking, bad season.

A PRETTY FAIR REPORT, "CONSIDERING."

As others are sending in reports, good and bad, some even worse than mine, I will let you have my first year's experience in apiculture. I commenced in July, 1883, with one colony in a boot-box, for which colony I paid \$3.00. They were black and cross. I transferred them a few days after getting them home, into a Simplicity hive, then bought a tested Italian queen of Dr. Griffith, for the sum of \$2.00; that changed the color and also the temper of that colony. One colony did not satisfy me, however, so I bought all the bees for sale near me, until I had 65 colonies. Among them were several colonies of blacks; but most were Italians. Several were as good as I ever saw. I took two colonies to the Belleville Fair and was awarded first premium. I have now almost got through Italianizing, and want no more blacks. The honey crop was rather short this last season, but I can not complain, as several of my best colonies gave me from 100 to 200 lbs. surplus, which was the result of early spring feeding, having the brood-chamber crowded with bees at the approach of white-clover bloom.

A WORD IN FAVOR OF SEPARATORS.

My first year's experience with sections (for I worked only for comb honey) leads me to the conclusion that friend Hutchinson knows what he is talking about when he says that separators can be dispensed with. I used them in 20 hives, with the poorest result. Those without separators went to work first, and finished their work best. Bees are all right up to date.

W. M. ROSS, 65-80.

Lebanon, Ills., Dec. 24, 1884.

Friend R., you did splendidly, especially considering the risk you ran in going in so heavily the first season. And now let me advise, or, rather, caution you, that if you do not look out you will have trouble next season. If you succeed in wintering well, I should say it will be safer for you to work for honey, and not continue to increase very much, until you get a little older in the business.

REPORTS DISCOURAGING.

I DON'T know but I am a candidate for Blasted Hopes just now. What bees I have (now united down to 12 swarms) I took from a man who owed me \$12.00, because I knew if I didn't take them I would never get any thing; and for lack of means to feed and care for them properly, I suppose they will die this winter. That isn't the worst feature of my "Blasted Hopishness," however. Over a year ago I had sufficient confidence in his honor to indorse notes with him to the amount of about \$150. I have already had to pay \$10 of it, and expect to have to pay the rest; and as I already had a pretty good load of debts of my own, I don't know but it will "smash" me. What makes me especially provoked with him is the fact, that although he can not pay a cent he can and does buy and chew nearly a dollar's worth of the very highest-priced tobacco every week, even if his children have to go destitute of necessary clothing, etc. Brother Root, go on in your good work against the abominable stuff. I am not as good a Christian as you are; and sometimes when I think of such things I lose some temper, and say hard words. Don't print this, friend R., at least not with my name or address. I suppose probably it is foolish to write any thing about it; but you always seem to be so friendly to everybody that it seems like talking to an old acquaintance.

X. Y. Z.

Friend X. Y. Z., do not get blue over your misfortunes. There is a moral to your story that may do somebody else some good, if it does not help you any; and the moral is, to stand on your own feet. Never ask anybody to indorse with you, if it is a possible thing to avoid it, and then you never need indorse with anybody else. If any of your friends feel hurt, and take offense because you refuse to do such a favor for them, they are not real *true* friends. Very likely, sooner or later they will be glad you did refuse to accommodate them. Don't ever let such a thought enter your head as being "smashed." I am fully convinced that people sometimes give up, and let things go, when resolute holding-on would put them in good shape. Now, just mind what I say, will you? Let this be a lesson for you, but do not give up one bit.

SOMETHING ABOUT THE REASON WHY WE DO NOT GET ANY MORE THAN WE DO.

To-day, on Thanksgiving-day, I feel inclined to think more about Blasted Hopes than about thanks, as the season around here can be called a poor one. I began the season with 18 colonies, and had 15 swarms, so that I have now 33 colonies. These gave me 354 lbs. comb honey, and 150 lbs. extracted. I don't think many bee-keepers from this part of the country will report, as the honey-crop is a very small one. A while ago I had a talk with a stranger, whom I happened to meet, and who claimed to be a bee-keeper with 80 colonies. While talking I asked him if he reported his honey crop; he said:

"No, sir, I won't."

Inquiring more, he replied:

"Yes, if it had been a good year I would have reported; but if I look at the bee-papers, and find that some who had a large crop say that they had so and so many years' experience, and they had managed so as to have much surplus; meaning that, on

the other hand, they who got only 10 lbs. surplus per colony don't understand the business, and that keeps many from reporting, any way. Even with the experience of 100 years, and a management superior to all others, if there is no nectar in the flowers, nobody can expect much."

He turned, and said good-by. I asked his name; but he said, "No, sir; I won't tell you my name, lest you mention it in one of those papers; but perhaps next year, if I should have a good crop, I will tell you, and report myself. It depends on our Lord's blessing."

So he left me, and I had to think about it.

Harvard, Ill., Nov. 27, 1884.

CHAS. FAUST.

Friend F., I know it is much as you say; but it is not only so in bee culture, but in every thing else, and I don't know how to remedy it either, so long as the friends declare they won't report.

BEE CULTURE IN FLORIDA.

A REPORT FROM ONE OF THE GIRLS WHO FORMERLY HELPED US IN THE OFFICE.

I AM still happy in the work with the bees. I am now rearing queens; and with a supply of pure drones, and at a time when wild or common bees are taking their winter rest, I keep mine working by feeding.

THE SPIDER PLANT IN FLORIDA.

Plenty of pollen coming in, and one large spider plant that I succeeded in keeping over the hot season is now full of bloom, and starts the bees out at 5 P. M., very much like robbing. I should be glad to have an acre blooming now.

THE PARTRIDGE PEA.

During the season of the partridge-pea bloom, the bees paid no attention to figwort or spider plant, or even the dripping banana-blooms, though the amount of honey seen on pea-bloom seemed very small beside the other plants.

I inclose a sample of bloom of partridge pea; I also send a small package of seed, as I think you would like to try it, perhaps.

Mr. Hart, of Smyrna, does not have much faith in the high pine land for bees; but I have found a long list of honey-producing plants in this region; and with the cultivated groves and gardens, and the delightful sunshine, bees certainly ought to do well, and I believe they will.

I scatter your price lists among neighbors, and there seems to be quite a boom for bees this year in Florida.

NELLIE ADAMS.

Sorrento, Florida, Dec., 1884.

Thanks for your report, friend Nellie. And it is really true, is it, that one who used to work at a desk right among us is now succeeding in that far-off land of flowers? By the way, does not the spider plant grow continuously from year to year with you? I have been told, that in California, tomatoes grow like a shrub, and keep bearing; and as the spider plant is so like the tomato in its habits, I should suppose this would be the case, and that if supplied with plenty of water it would bloom for months uninterruptedly. Can you tell us if this is so? We want to know more about that banana with dripping blooms. You speak of feeding. About how many months in the year will your bees take feed? Certainly not when these plants you mention are in bloom?

FRIEND BAUM'S TROUBLE.

FEEDING BEES WHILE THEY ARE IN THE CELLAR. ETC.

I HAVE been wanting to write to you for some time, but I dislike to bother a man as kind as I think you are. But the last GLEANINGS was too much for me, where you speak about asking advice of an old farmer. Now, I am an old soldier, and not able to do much work, in consequence of a disability contracted in the army. I am neither poor nor rich, but have a good little farm, a good wife, and three little boys. Two years ago I thought I would try bees, and paid \$50.00 for ten good strong stands of bees. Well, I was green; but I increased to 30, and sold \$75.00 worth of comb honey, and had plenty for my own table. Then I had such glorious fun in hiving the new swarms, and lost only the first one.

Late in the fall I put them in my cellar, which is very large; and when spring came I had lost one. I put them out, and then lost five or six by spring dwindling. I could have saved them, if I had had sense enough to feed them. But, all right so far.

This summer we have made but little honey; and this fall I found I had 14 that had but little honey. I got a barrel of A sugar, and fed them as they seemed to need it. I fed them by putting the syrup in shallow pans on top of the frames, but under the hood or upper story. I fed at night to avoid robbers. Two weeks ago I put them in the cellar, and since they have been in there they won't eat their feed. They seem to be lively, but I know they have almost no honey. Now, I have bothered you all this time to ask you, "How shall I get them to eat?" I do not wish to double them up, and I should like to keep them until spring, for I know that bees will be scarce here in the spring. I keep the cellar dark.

GERMAN CARP.

I see you have a carp-pond too. I have had one two years. We took out several this fall to eat. They were about 18 inches long. They are not a very good fish, but still they do to eat. We still have one in a box, that we expect to eat on Christmas.

GEORGE W. BAUM.

Delphi, Ind., Dec. 22, 1884.

Why, friend B., you have been through one winter and summer, and, I should say, managed nicely. It would have been better, of course, had you commenced feeding a little earlier. Your plan of feeding was all right, and a very few days with such an arrangement ought to have given them enough for winter. There seems to be a difficulty in feeding bees in the cellar; for even if they do take it, it is apt to make them uneasy and discontented. Are you sure they have not enough to last them until we have warm weather enough so you can set them out for a fly? After the flight they will eat the feed all right without any trouble. You might try feeding candy, as advised in the A B C book, and in our recent back numbers.—Thanks for your item about the carp-pond. But, you are the first one who has reported that carp are not very good for food. So they can be kept some time in a box or tub, can they? This is an important item.—I think your bees will certainly take the syrup, especially if made quite thick, before they will starve. They will certainly eat candy any way, if you put it in small lumps right over the cluster.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT.

EDITOR AND PUBLISHER.
MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, JAN. 1, 1885.

Bees was as serpent, and harmless as doves. —MATT. 10: 16.

We will pay 10 cts. for April 1 GLEANINGS, 1884.

WE are happy to tell you that we commence the new year with 5145 names. You may remember, that last year we started with 4275. May God bless you, friends, for the ready support you have given my poor efforts in your behalf.

SMITH'S HONEY-RACK.

THE honey-rack shown on page 841, last issue, belonging to friend Smith, we shall not offer for sale, as he prefers to supply the trade himself. His circular, which he will be glad to mail you, gives full prices and particulars as to how the racks are to be used.

DECLINE IN PRICES.

I ALWAYS feel happy when I can offer you certain lines of goods that are greatly called for, at a reduction. Now it seems to me, friends, it is a pretty good idea to have a journal that is able to tell you twice a month all about the decline in prices of such things as bee-keepers are obliged to buy, more or less. Don't you think so?

REDUCTION IN HALF-POUND JELLY-TUMBLERS.

WE can now furnish a neater and prettier tumbler than we ever had before for 3 cts. each, 25 cts. for 10, \$2.40 per 100, or \$22.50 per 1000. These are what are usually sold as jelly-tumblers with tin top. By laying on a piece of paper of the proper thickness, before the top is put on, the tumblers can be shut as tight as a corked bottle.

MUELLER'S LIFE OF TRUST.

IT has always pained me, in showing this book and explaining it to friends who were learning to trust in God, to be obliged to tell them the price was so high. We are now enabled to offer it, neatly bound in cloth, for only 60 cts. If wanted by mail, postage will be 10 cts. extra. This is the latest edition, with engravings of all the buildings, etc.

DISCOUNTS UNTIL JANUARY 15.

INSTEAD of 3 per cent, the discount will be 2 per cent off on orders for goods of any description, received before Jan. 15. The regular discount of 10 per cent that we have been giving on fdn. and sections will also be held open until Jan. 15. We do this as an inducement for sending orders now instead of during the rush a little later. The offer of 10,000 Simplicity sections for \$10.00 is also continued till the fifteenth.

DATE*YOUR PRICE LISTS AND CIRCULARS.

AS for me, I like to see every thing dated, and I like to see advertisements and circulars tell what time of year the goods are fit to send out. I have been watching price lists of plants lately, to see at what time of year small-fruit men are ready to

send out strawberry and raspberry plants; but there is not a single circular that tells when they will be ready. It is just my luck to be sending for something out of season. Why not state in your price list just when you will be ready to send strawberries, eggs for hatching, carp for stocking ponds, etc.? You see, we are green in the business, and are almost always "wanting to know, you know."

BEES AND CIDER-MILLS.

ONE of our bee conventions proposes to petition the Legislature to abate the nuisance of cider-mills; that is, the nuisance to bee-keepers. I am afraid, friends, if you start out that way the cider-mill men will be sending a petition to have the nuisance of bee-keeping abated. The bee-friends suggest that the cider-mill men be obliged to keep the bees out by screens of wire cloth. Well, such screens will fix the matter, without doubt; but, who is to pay for them? The friendly way would be to divide the expense between both parties, or let the party making the most complaint bear the larger part of the expense. I think, for the sake of peace and harmony, I would furnish the wire cloth and put it on myself. It seems a sad thing for neighbors to appeal to law or legislation in defense of their separate industries.

SPIDER PLANT AND FIGWORT.

IT is a fact, friends, that if you want to have either of the above plants in perfection the first year, they must be started in a greenhouse, or in boxes by the window. By doing this you will get figwort to yield a full crop of honey the first year, and the spider plant may be made to commence blossoming outdoors in June; and if the ground is rich and deep, the plants will grow to a monstrous size by September or October. It is a peculiarity of the spider plant, that it continues to grow and put forth blossoms just as long as the season will permit. So long as the present demand for the seeds continues, these will pay all expense of cultivation, to say nothing about the honey. If any one can furnish us seed of the *Epilobium angustifolium*, or, in fact, any one of this family of "purple fireweeds," as they are sometimes called, we shall be very glad to get them. See engravings on page 726.

A VERY PRETTY PRICE LIST FOR A SMALL SUM OF MONEY.

FRIEND A. L. Swinson, of Goldsboro, N. C., has just had a very neat job done at our office, in the way of a price list on a single sheet of GLEANINGS paper. He had 20 lbs. of paper, which makes about 4000 sheets. The regular rate would be \$5.00; but as about two-thirds of the sheet was covered with matter in fine type, we charged him \$8.00 for the 4000. This would be at the rate of 5 circulars for a cent. The unoccupied portion of the sheet forms the letter-head, and it is closely ruled, so that a good deal of matter can be put on when need be. The blank side of the sheet can also be used for writing, so that friend S. can give every correspondent a price list every time he writes. If you want to see what a neat job we can get up for five for a cent, just ask friend S. for a sample. Of course, we can not furnish them at this very low price unless 4000 or 5000 are ordered at a time.

A PRACTICAL TREATISE ON BEE CULTURE.

THIS is the title of a new book from our friend Rev. Wm. Ballantine, of Sago, O. Although the book does not contain much that is new, friend B.

has done his work well, for he is a man of talent and education, and, I believe, a successful bee-keeper. One of the new features we find in the book is a home-made circular saw, illustrated and described. The engraver has, however, made very bad work in picturing the implement, and I am sorry to say that his printers have done wretchedly in the get-up of the book. I do not believe it pays, friends, to have books made at offices unaccustomed to such work. Perhaps friend B. will have out a new edition soon, with these typographical errors and faulty presswork remedied. Perhaps these things will not be noticed so much by those who do not make printing a business. The book is mailed, in paper covers, for 50 cts.; cloth bound, 75 cts. See advertisement.

THE PROSPECTS FOR 1885.

GLEANINGS, with all its faults and failings, even during this time of general depression in business, is already beyond what it ever was before in the way of a subscription list. I feel very grateful, friends, to think we are able to start out with the first issue with almost a full subscription list. Our mails are so heavy now that it is about all I can do to read the *business* part of it each day, let alone reading the articles that are contributed for publication. A great portion of these will doubtless have to wait until a little later in the season before we can find a place for them, as has happened almost every year of late. When the friends send in their subscription it comes quite natural for them to send a report or article, and we are glad to have them do so; and even though we can not use them all as soon as they appear, they are, most of them, just as valuable a few months later. It has been the general impression, that 1884 had given a rather poor crop of honey; but the reports that come in with the subscriptions seem to me to indicate that the crop has been at least a fair one. There are bee-keepers enough in our land to give a fair support to all the journals; and bee-journals, like individuals, differ widely. Therefore, friends, if one journal does not please you, quietly drop it and take another. So far as I am concerned I do not expect—in fact, it would be strange if GLEANINGS did suit everybody. For my part I am quite willing you should take some other, if you prefer it; and whenever I meet you I will try to be just as willing to extend a neighborly hand as if you were one of our own subscribers.

GROOVING SAWS THAT SMOKE.

SEVERAL of the friends speak about having trouble with saws for grooving the ends of the bolt of plank for making section boxes. The trouble is, that you have too many teeth in your saws, or they are not filed in the proper shape. Now, then, friends, it is very important to have this matter exact. We have had years of experience, and know all about it; and if you do just as I tell you your teeth won't smoke, and one man can push the bolts over the saw, without fatigue either. The teeth must be large. Small ones fill with dust, and clog up. For a six-inch grooving saw, the points of the teeth should be fully three-fourths of an inch apart, and they must be filed so the shape will be according to the diagrams given in the ABC book. We have sent out saws that were not made as they should be, before we knew any better. In many cases the best way to fix the saw will be to take out every other tooth. If they are a little more than three-fourths

of an inch apart, it would not matter. A good stout gummer or emery-wheel is then needed. Where the fault has been ours, I will pay the expense of fixing them.

DAMAGING A BEE-KEEPER'S REPUTATION BY ACCUSING HIM OF ADULTERATING HIS HONEY.

My friends, if your reputation is what it ought to be, I do not believe a slander can hurt you in the long run, to any great extent. Such stories do not often stick long to the name of a good man. Instead of getting greatly stirred up about this matter of adulteration, be so frank and open in your business, and so willing to let everybody see what you are doing, and how you do it, that when any such charge is made against you it will of itself recoil back on the one who started it. I can not remember that I ever knew a good man very much hurt by stories circulated about him. There are people in almost every neighborhood, whose standing is such that nobody thinks of accusing them of such work. Well, your business is to set quietly about it and make yourself one of that kind of people; and then if anybody accuses you wrongfully it will be like throwing muddy water on a duck's back. It will slip off so quick that nobody will notice it, and even you yourself will not be conscious of having been harmed.

BEES AND QUEENS DURING 1884.

OUR queen-clerk reports as follows: Queens sold during 1884, 3506. Of the above number, 2408 were untested queens. Pounds of bees sold, 470. As a great part of them (perhaps the greater part of the bees and queens) were sold during the spring months, the average price would be perhaps \$1.50 each for the untested, and, say, \$3.00 each for the tested queens. The average price of bees by the pound was perhaps \$3.00, making a sum total of bees and queens about \$8356. The tested and select tested queens were all reared in our own apiary, or in that of Neighbor H.; but it is impossible to say how many of the untested queens we reared, as in the early spring months we bought queens from the South in large quantities, and introduced them to our hives. Probably one-half of the whole number of untested were of our own raising; therefore if we deduct \$1800 for untested queens purchased from the South, we shall have about \$6780 as the proceeds of our own apiary, devoted entirely to raising bees and queens for the market. We commenced the season with about 150 colonies, and added by purchase, 125; so you can form some idea how well it pays to rear bees and queens for the market. Labor all together cost perhaps \$1000, including cost of correspondence.

CARP IN OHIO.

Two or three years ago, Mr. E. B. Blakeslee, a neighbor living within a mile or two, got some German carp, and put them in a pond containing perhaps 1½ acres. Mr. B. is one of our bee-keeping friends, as many of you may remember. Well, I had not heard about his carp for some time, but to-day he informs me that his pond is so full there is hardly room for all of them, and that in warm weather they may be seen along the shores in great numbers. If you keep perfectly still, great big fellows will rise up in full sight, but disappear at the first movement. And now comes the wonderful part of friend B.'s fish story. If you keep still long enough, you may often see them stick their heads out of the water along the banks, to pick grass:

and when I laughed at this new feature, he said with great earnestness he could assure me the herbage was kept clean, clear around the pond. You see, they want vegetable food, and he has not provided it for them, and so they come around the water's edge as cows go around the corn-field, nipping off every thing within reach. He says they are the best fish for food he ever ate in his life. They have used perhaps half a dozen of them, some of them great big strapping fellows. His pond has no running stream, but is simply a cavity between the hills, filled with rain water. He has had a large-sized carp for some time in a large tub or tank, perhaps 8 feet across, where he waters his cattle and horses, and his dog sometimes tries to worry it. The carp and dog make a regular show of fight on both sides. When you come to see me we will take the horse and buggy, and go over and look at all these funny things, providing it is warm weather.

SUPPLY DEALERS, AND THE BRADSTREET MERCANTILE AGENCY.

OUR friends may not all be aware, that as soon as they get to doing business, and begin to advertise bee-supplies, their standing will soon be quoted in Bradstreet's Mercantile Agency. As a rule, these different agencies endeavor to give the best report of a man that they can consistently; that is, without doing harm by recommending a man who is not worthy of confidence. I need hardly say, that it behooves every one to work for a good record or report. Well, we are, at the present time, having quite a little business with the Bradstreet Company; and as we are better able, perhaps, to quote the standing of the bee-keepers than any other institution in the world, this company desires us to correct their reports when they are wrong. Now, I am very sorry to be obliged to tell them that they have got any bee-man too high; but when public safety demands it, we shall do this without fear or favor. The man who will not answer inquiries in regard to bills he is owing is not worthy of being reported trustworthy. A year ago I mentioned that there were two parties contracting debts for honey, who could not or would not pay. I believe these two parties have made no new debts since then; but there are one or two others whose names have appeared in the bee-journals, even in the pages of GLEANINGS; and these men have obtained credit, probably because we had permitted their articles to appear in print, and it begins to look as though public safety demanded that our friends should be warned against trusting them. I shall be very sorry, as I have told you, to be obliged to do this; but it is not only right and proper, but it is customary in all kinds of business. It has often been said, that bee-men are a little above the average in intelligence and respectability. Can't we keep so clean a record that the same may be said in regard to promptness and responsibility?

ADS TO THOSE WHO FIND THEIR CORRESPONDENCE BURDENSOME.

WHENEVER you have occasion to write to certain parties frequently, it will be quite a help to have addressed and stamped envelopes lying handy, so that all you have to do is to slip your letter into one of these envelopes, and it is ready for the postoffice. This also saves mistakes in addressing your matter. Quite a breeze happened at our postoffice a few days ago, because a man sent a letter containing money, and forgot to put on the State. Another

party even sent for the postoffice detectives, to have them recover a lost letter; and when found, the woman who sent it addressed it, by mistake, to a firm that had no existence. Now, then, how shall we get a supply of envelopes and postal cards with the addresses plainly printed? Why, let each man who has something to sell furnish them to his customers free. Our clerk who sends out orders, by my advice wrote to the principal firms of whom we buy goods, and asked for a few envelopes bearing their name and address. Almost without exception they came promptly; and where we have been in the habit of sending a good many orders, they were all stamped ready to mail. We finally found we had so many of them, that Mr. Gray made a sort of revolving book-rack, with pigeon-holes in it. There are 48 of the pigeon-holes, and a great part of them are now full, and the stamps that are on the envelopes will go a good way toward paying for the whole institution. Now, then, if we want to get an order off in a hurry, we just jot it down on a piece of paper, and push it into the proper envelope, and it is all ready for the postoffice. Any man who is doing business can well afford to furnish stamped envelopes to those who buy goods of him. Another thing: It takes a mental effort to remember addresses, and write them right. By the arrangement I have suggested, a great part of the labor of correspondence is done by the printing-press, and done nicely. Every clerk in the office now has envelopes and postal cards printed to all parties with whom she is likely to have much business.

CONVENTION NOTICES.

The Champlain-Valley Bee-Keepers' Association will meet at Addison House, Middlebury, Vt., on Thursday, Jan. 8, 1885. J. E. CRANE, Sec.

The annual meeting of the Maine Bee-Keepers' Association will be held at Dexter, Me., Jan. 20, 21, and 22. F. O. ADAMS, Pres. WM. HOYT, Sec.

The 7th annual meeting of the Nebraska State B. K. A. will be held at Tecumseh, Neb., on Wed., Thurs., and Friday, Jan. 14, 15, and 16, 1885. M. L. TRESTER, Sec.

The Mahoning-Valley Bee-Keepers' Association will hold its next meeting in the Town Hall at Newton Falls, on the third Thursday, Jan. 15, 1885. The meeting will be instructive as well as interesting. Lordstown, O., Dec. 15, 1884. E. W. TURNER, Sec.

The North-Eastern Ohio and North-Western Pa. Bee-keepers' Association will hold its sixth annual convention in the Y. M. C. A. Rooms, corner of 10th and Peach Sts., Erie, Pa., Wednesday and Thursday, Jan. 14th and 15th, 1885. First-class hotel accommodations at the Wilcox House, \$1.00 per day, to those attending the convention. A general invitation is extended to all. C. H. COON, Sec. New Lyme, Ohio.

NORTH-EASTERN BEE-KEEPERS' CONVENTION.

The sixteenth annual convention of the North-Eastern Bee-Keepers' Association will be held in the City Hall at Syracuse, N. Y., on the 21st, 22d, and 23d days of January, 1885. The executive committee are determined to maintain the high standing and enviable reputation the association has justly gained in the past, and proposes to outdo all former efforts, at the coming convention. The meeting will surely be the largest and most interesting ever held in America. No bee-keeper can afford to stay at home. All are invited. All implements of the apian sent to the society will be properly arranged, to compare favorably with others on exhibition, and will be disposed of or returned as the owner directs. Reduced rates for board at hotels. L. C. ROOT, Pres.

GEO. W. HOUSE, Sec.

APIARY FOR SALE.

In good location, with 70 colonies of bees, all in first-class condition, all on Simplicity frames; with 3 imported queens, my own importation. My reason for selling is, I have a large apiary in Southern Arkansas, and it is too far to give attention to both of them. If anybody wants to buy a good apiary, with fixtures, every thing that you want and need, hives, sections, honey-extractor, honey-knives, smoker, 150 hives, etc., here is a good chance. Bees are Italian, Holy-Land, and Syrian. All first-class. Price on application. Address

LOUIS WERNER,

24-12d Edwardsville, Madison Co., Ill.

QUEENS BY RETURN MAIL. I am now up with my orders, and can send by return mail. Send me your orders and help me out of the fire. J. T. WILSON, Nicholasville, Jessamine Co., Ky.

PASTEBOARD BOXES

FOR ONE-POUND SECTIONS OF

COMB HONEY.

This box has a bit of "red tape" attached to it to carry it by. It makes a safe package for a single section of honey for the consumer to carry, or it can be packed in a trunk, if he wants. It can be opened in an instant. The price of the box is 2 cts. each, set up; in the flat, 15 cts. for 10; package of 25, 35 cts.; \$1.20 per 100; or \$11.00 per 1000; 10.0-0, \$10.0. Colored lithograph labels for putting on the sides, two kinds, one for each side, \$3.50 per 1000. A package of 25, labeled on both sides, as above, 60 cts. By mail, 30 cts. more. They can be sold, labeled on one side or both sides, of course. We have only one size in stock, for Simplicity sections. Sample by mail, with a label on each side, 5 cts. If you want them shipped in the flat, labels already pasted on, the price will be one cent each additional, for labels.

A. I. ROOT, Medina, Ohio.

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

Such a brisk demand has sprung up for this, and our customers seem to be so much pleased with the goods, we have succeeded in getting another still larger lot, one of the largest manufacturers of wire cloth in the world. Please bear in mind that the only way in which we can afford to sell it at the very low price of 1 1/2 cts. per sq. ft. is by selling the entire remnant just as it is put up. We have now in stock the following pieces. As fast as it is sold, each piece is crossed out, and the next issue will show what remains.

Width, 8 inches. 3 rolls containing respectively 50, 50, and 60 square feet.
Width 10 inches.—1 roll, containing respectively 72, 70, 65, and 75 square feet.
Width, 11 inches.—One roll, containing 80 square feet.
Width 12 inches.—5 rolls, containing respectively, 80, 100, 90, 90, and 100 square feet.
Width, 14 inches.—1 roll, containing 116 square feet.
Width, 16 inches.—4 rolls, containing respectively, 60, 150, 130, and 148 square feet.
Width, 20 inches.—1 roll, containing 150 square feet.
Width, 22 inches.—2 rolls, containing respectively, 250, and 180 square feet.
Width, 24 inches. 11 rolls, containing respectively, 50, 55, 72, 20, 20, 30, 80, 110, 60, 110, and 200 square feet.
Width, 25 inches.—5 rolls, containing respectively, 53, 97, 100, 143, and 250 square feet.
Width, 26 inches.—13 rolls, containing respectively, 69, 215, 40, 40, 200, 210, 210, 200, 215, 216, 65, 200, and 200 square feet.
Width, 27 inches.—One to 1, containing 23 square feet.
Width, 28 inches.—11 rolls, containing respectively, 58, 93, 125, 116, 200, and 140, 200, 200, 190 and 274 square feet.
Width, 29 inches. 9 rolls, containing respectively, 110, 210, 25, 72, 90, 190, 62, 210, and 115 square feet.
Width, 32 inches.—3 rolls, containing respectively, 150, 172, 125, 41, and 152 square feet.
Width 34 inches.—4 rolls, containing respectively, 265, 270, 85 and 120 square feet.
Width 36 inches.—7 rolls, containing respectively, 80, 270, 200, 60, 150, 120, and 170 square feet.
Width, 38 inches.—5 rolls, containing respectively, 75, 316, 360, 290 and 316 square feet.
Width, 40 inches.—5 rolls, containing respectively, 300, 275, 320, 160, and 125 square feet.
Width, 42 inches.—One roll, containing 245 square feet.
Width, 48 inches.—One roll, containing 140 square feet.

CONVENTION NOTICES.

The Cortland Union Bee-Keepers' Association will hold their next meeting in Cortland, Jan. 27, 1885.
M. G. DARBY, Sec.

The annual meeting of the Maine Bee-Keepers' Association will be held at Dexter, Me., Jan. 20, 21, and 22.
F. O. ADDIXON, Pres.
WM. HOYT, Sec.

The Bee-Keepers' Association of Hamilton and Tipton Counties, Ind., will hold its next meeting at Cicero, Hamilton Co., on Friday, Feb. 6, 1885.
JNO. FRITZ, Sec. D. AMING, Pres.

The sixteenth annual convention of the North Eastern Bee-Keepers' Association will be held in the City Hall at Syracuse, N. Y., on the 21st, 22d, and 23d days of January, 1885.
L. C. ROOT, Pres.
GEO. W. HOUSE, Sec.

The Northwestern Mich. Bee-Keepers' Association will hold its third annual convention Feb. 4th, 1885, at Vassar. Place for holding meeting will be given in Feb. GLEANINGS. Send to the Secretary for railroad certificates, and secure reduced rates.
W. Z. HUTCHINSON, Sec.

THE WORLD'S BEE-KEEPERS' CONVENTION.

THIS is to be held at New Orleans, on Tuesday, Wednesday, and Thursday, Feb. 24, 25, and 26, 1885. The bee-keepers of the world are invited to attend the convention and exhibit, to be held on the above days. We have put it before you in the above shape so you will be sure not to forget it. If there is any part of the world that is not cordially invited, the managers will please correct.

ED. GLEANINGS.

SEVERAL ITEMS FROM FRIEND POP- PLETON.

FORMING NUCLEI, MARKING HIVES, SOLAR WAX-
EXTRACTOR, ETC.

ON page 875, last issue of GLEANINGS, Mr. Doolittle gives us something which I think will prove of very great value to bee-keepers, but not for the purpose he tells of. I use and am well satisfied with the simpler method of uniting nuclei that is in common use; but I hope we shall find the method he describes, to be almost a perfect one for the formation or making of nuclei. We all know how much better results we get from nuclei which contain a proper proportion of both old and young bees, and also how very difficult it is to get many old bees to remain in nuclei formed at home. This difficulty is so great that last year I took a few colonies three or four miles from home, and from them obtained the most of my nuclei. Nuclei formed in this manner gave so much better results than when formed by the old method. I had intended to follow it this coming season, but I shall test this method given by Mr. Doolittle; and if it results in keeping the old bees with the newly formed nuclei as well as it seems reasonable to suppose it will, I for one will feel very much indebted to Mr. D. for his hints, although not put to the uses that he advised.

ATTENTION-MARKS ON HIVES.

I think it was also Mr. Doolittle who some time ago mentioned the fact that he used stones or sticks placed on different parts of a hive to indicate that some particular work needed doing at a suitable opportunity; thus, if during his regular work he finds a colony with a poor queen that ought to be superseded, he places a stone or block on some par-

ticular part of the hive, and on some other part of the hive if some other particular work needs to be done; then when he has time to attend to these things he can see at a glance just what and where any thing needs doing, without taking time to hunt up the work, or running any risk of overlooking necessary work. This is exactly similar to what I have myself used for several years, but have lately used a device much plainer, and yet very simple. It is a marker, made by nailing one piece of board across the end of another piece, being, when made, a perfect T in shape, the stem being much heavier than the top piece. I usually make the stem out of inch stuff, about 2 inches wide by 10 or 12 long, the top piece being half inch or thinner, same width as stem, and about 6 inches long. One end of the top piece is painted green or blue, the other end red. These blocks are very slightly, and can be made to indicate a large number of meanings by placing them on different parts of hives; and if necessary, by changing the position of the colors; as, red over green indicates one thing, and green over red something else. These blocks are very easily and cheaply made, as they can usually be manufactured out of waste pieces of lumber lying around the shop, and on some rainy or spare day. I have used these blocks during the past season, and find they are quite a saving of both time and steps.

CARE OF SMOKERS.

Some two or three years ago I came very near sustaining a heavy loss by fire, caused, by accidentally dropping a spark while refilling my smoker in the shop. This taught me a lesson, and since then I do not allow smokers to be taken into the shop at all, but keep them in a box near the center of the apiary, made on purpose. This box is well painted

and covered, and large enough to contain smokers, matches, shavings, and smoker fuel enough to last two or three days.

SOLAR WAX-EXTRACTORS.

Since the description of the Sun wax-extractor which I have used for years was published in 1883, page 521, I have noticed several descriptions of improvements, so called. All these improvements I have so far seen described are, I think, of more detriment to the value of the instrument than benefit. All were in reference to some method of straining the melted wax from the refuse. Any wire cloth or sieve that may be in the extractor to strain the wax through, must obstruct the sun's rays more or less, which is a positive detriment, while the object attained is of little or no value, as the wax being kept melted for a length of time allows all the refuse to settle to the bottom, when the wax can be dipped off in an almost absolutely pure condition with the flat sided tin cup, described in the original article.

I also see that some make their extractors in such a manner that the pan, or whatever is used to catch the melted wax as it drops from the wax-holder, is not left exposed to the sun's rays enough to keep the wax in it in a melted condition, thus preventing the wax from settling, or, rather, clarifying itself, which I consider one of the prime objects of the implement, second only to the actual melting of the wax.

I mentioned the fact in my original article, that the wax rendered in the Solar wax-extractor was harder than when rendered by other means, which *might* be an objection. I am informed by Mr. Thos. Tracy, of Nashua, Iowa, who runs a foundation-mill, that, instead of being an objection, he finds the wax so rendered to be tougher and better than other kinds of wax. Mr. Tracy uses a simple system of reflectors, which increases the efficiency of the implement, besides allowing us to use a single instead of double glass. He hinges the board cover, made to cover the implement when not in use, to the upper end of the sash, having first lined the inside of the cover with bright tin. This can be raised and fastened at any angle desired. Another cover, made and lined with tin like the first one, is then hinged to the side of the extractor in such a manner that it can be easily attached to either side of it, and held in a perpendicular position by hooks and staples connecting it with the first-mentioned cover. The detachable hinges for the side reflector can be very easily made by driving some staples into the edges of the sash, and some half-bent pieces of No. 9 wire into the bottom edge of the reflector. The side reflector will, of course, have to be on the west side of the implement in the forenoon, and on the east side in the afternoon, and can be laid, when not in use, tin side down, on top of the implement after shutting down the real cover.

O. O. POPPLETON, 114-236.

Williamstown, Iowa, Jan. 5, 1885.

Thanks, friend P. We can often find at the drug-stores square tin cans, used for holding castor oil and other substances. One of these laid on its side, with one end cut open, makes an excellent receptacle for a smoker, rotten wood, etc. It keeps out the rain, and no danger of fire. It can be nailed up against the fence, or a post, or anywhere in the apiary.—In regard to the Solar wax-extractor, it seems to me some of our implement-dealers might get up one for

sale. Of course, they could be made a good deal cheaper where 25 or 100 were made at one time. These reflectors to throw the sun on to the wax are quite an improvement. If tin is used, the reflectors would have to be carried in before a storm, or they would get rusted so as to spoil their efficiency. A cheap looking-glass plate would give still more heat. If the whole were put under a shed that would admit the sun, but exclude wind and rain, it might always be in working order, and would be found, I think, a profitable investment.

MICHIGAN STATE CONVENTION.

WHAT I SAW AND LEARNED.—NO. 2.

WHEN I stepped from the train, the first thing was to inquire of somebody where the convention was to be held. One might naturally suppose that we editors know every thing published in our papers; but I for one find it necessary to refer to GLEANINGS almost constantly, to know what I have written and what others have written. As the convention was to be held in the State-house, and as the Statehouse is a very prominent object in the city of Lansing, it did not take me long to get there. I was told the convention was away up in some of the upper stories, and that I had better go up in the elevator. The elevator was just starting, pretty nearly full; but I got on, and whom do you suppose I ran against first? Why, Prof. Cook himself! It always gives me pleasure to hear that people are expecting me, and are glad to see me; therefore I started out pretty well pleased. Friend Cook stopped the elevator, and we did not go away up in the attic; but by some new arrangement which I did not understand, we straightway gathered in the Senate chamber; at least that is what they called it, if I remember correctly. It was a most beautiful room, any way. By the way, how pleasant it does make any thing in the way of conventions go off, to have a nice commodious room! The room was nice, and the people were nice, and they all behaved themselves nicely. If Huber had been there I suppose he would have ejaculated very soon, "Papa, ain't it ni'y?"

The convention opened up full of interest at the outset.

REVERSIBLE FRAMES.

The facts given for and against these enlisted my closest attention at once. The question was taken up on both sides, by those who are not only old in the honey business, but who are keen and sharp as well. A great mass of evidence was given on both sides of the question, and several reasons were brought forward for using reversible frames, that I had not thought of. Very likely, reversible frames might do harm in the hands of a novice, because an unwise reversal results in about the same injury as does an unwise spreading of the brood-nest; that is, reversing the frames too early in the season, when the cluster is not strong enough to stand a breaking-up of the brood-nest, would perhaps do harm. But in the

hands of one who is old and experienced, it offers advantages that it seems to me we can not very well do without. Prof. Cook gave us a happy summing-up of the advantages and disadvantages. I did not take it all down, neither did any of the reporters, so far as I have been able to discover. Prof. Cook's strongest point was, perhaps, that by means of a reversible frame we can throw nearly all of the early white honey, clover and linden for instance, into section boxes, where it will command a price that will enable us to buy sugar two or three times over; and I was glad to hear Prof. Cook endorse the position I took so many years ago, that a pound of sugar would go further than a pound of honey, for wintering bees, and is at the same time much more wholesome. Reversible frames are destined to become largely used the coming season. A very practicable device is given in another column, and we will try to give engravings of it in our next issue.

WIDTH OF SECTIONS.

There seems to be a pretty general agreement, that where we wish to dispense with separators, the sections should be narrower than where separators are used. A width of section so that seven placed side by side will measure a foot across seems to have given good results.

SIZE OF SECTIONS.

The tendency was very strongly in favor of the one-pound sections, $4\frac{1}{2} \times 4\frac{1}{2}$, the size I decided upon years ago, so that eight would go inside of a Langstroth frame. The tendency in Michigan is quite strong, however, to abandon the idea of putting sections into frames at all. Setting them over the brood-nest in a case gives about as much honey, if properly handled, and is much less trouble; that is, those at the convention, as a rule, seemed to think so.

USING A HONEY-BOARD UNDER THE CASE OF SECTIONS.

It seems to me a little funny to think that bee-keepers are almost *en masse* now going back to the old discarded L. honey-board, with its bee-space under it. One of the principal claims in the Langstroth patent was this $\frac{1}{2}$ inch over the frames, for a bee-space; and for years we have thought it was a hindrance; but now, instead of thinking this $\frac{1}{2}$ inch to be a waste of space, two bee-spaces are given—one under the honey-board, and one above it. During the convention it was made plain to me for the first time, why people wanted this honey-board; and the reason seems to be this: The bees will build bridge-combs from the top of the brood-frames to the honey-board. We all know this, and some of us to our sorrow. Well, a great many assured me, and Prof. Cook among the number, that after having filled the first bee-space with bits of comb the bees seem satisfied, and did not put any comb and bits of wax between the top of the honey-board and the sections placed in a case right over the honey-board. In fact, a case of sections so arranged can be lifted off at any time for tiering up, sending to market, or any other purpose. Our one-armed friend, J. H. Robertson, assured me this was the

case, and that it was a great convenience with him, for it enabled him to take off the cases with one hand.

HOW TO MAKE A HONEY-BOARD.

President Hutchinson here spoke of having a honey-board made so that the spaces in it corresponded to those used in the perforated zinc, for keeping the queen and drones below. Wooden bars placed at proper distances apart would not be practicable, because the spaces could not be made sufficiently exact in this way, and the shrinkage of the boards would be constantly liable to make a variation in these spaces. Friend H. has, however, already suggested a remedy for this. In talking with Mr. R. L. Taylor, who passed the night at Prof. Cook's, with the rest of us, he informed me that he suggested the idea to friend H., who has succeeded perfectly in making a wooden honey-board with correct bee-spaces. Within a few days friend H. has sent us a honey-board by express, having bee-spaces made with a circular saw, which we furnished him, of the proper thickness. The adjoining cut gives

FIG. 1.

PERFORATED WOODEN HONEY-BOARD.

wood, the pieces being united at their ends by a cleat extending across both of them. These cleats, in order to give the proper bee-space, are exactly $\frac{1}{2}$ inch square. The boards forming the honey-board are perforated by dropping them over a gang of four circular saws properly spaced. The size is, of course, so made as to fill the top of the hive. Those we keep in stock are just right for the Simplicity or chaff hive. We can furnish them for 15 cts. each; \$1.35 for ten, or \$12.50 per 100. These prices are for the boards nailed up. In the flat they will be \$1.25 for ten, or \$11.00 per 100. A sample can be sent by mail for 12 cts. more for postage.

In working for extracted honey, I do not think I would use these honey-boards between the upper and lower stories. If you prefer to have the frames in the upper story contain nothing but honey, however, one of these honey-boards will accomplish it perfectly; and another thing, it also absolutely prevents the bees from building between the upper and lower frames; at least, the convention people intimated as much; that is, if we have a $\frac{1}{2}$ -inch space above and below the honey-board, the honey-board will likely be waxed down solid to the tops of the lower frames, but the upper frames will hang so as to be lifted out any time, without any attachments to the honey-board, any more than we have to the bottom-board of the hive.

Continued next month.

FIG. 2.

HOW DR. LOOPE SUCCEEDED IN BEE-KEEPING.

EVEN IF HE DID GO AND BUY A GREAT LOT IN THE OUTSET TO START WITH.

I AM, as you will presently see, a beginner in bee culture. I am not much given to troubling editors with my notions, so that you need not fear very frequent inflictions on your time and patience. Still, I belong to that rapidly increasing class called bee-keepers; and as you seem to wish reports, whether good or bad, I will send you mine.

I bought 50 swarms of bees in the spring of 1883, without previous knowledge or experience in the methods or devices pertaining to bee culture. However, I hired a lady who had some experience, and took counsel of others who were in the business, in the meantime subscribing for GLEANINGS, and reading Quinby and other works. I got about 2000 lbs. of comb honey, and increased to 90, as a result of that year's work. In the fall I bought 50 swarms more, and came out in the spring of 1884 with 110 colonies, 35 of which were mere nuclei, from bad wintering. The reason of such loss was, that the rats got into the cellar where my bees were; and before I found it out they were running riot among the hives, tearing off honey-boards, and gnawing the frames almost in two, to get at the honey. Of course this constant irritation produced dysentery, with consequent weakening and death. Of the 75 swarms not mere nuclei, there were not many that were strong; but the spring was quite favorable; and by June 10th I had them booming with my nuclei coming along in good shape. I depended on hired help to do most of the work, being myself busy in my profession; but I was fortunate in securing a man who could "catch on," and was steady and faithful.

The season in our locality was quite favorable, and it closed by giving me 8000 lbs. of choice white honey, basswood and clover, besides a considerable amount of unfinished sections and dark honey, probably aggregating 500 lbs., which will come very handy next spring. I increased to 183 swarms, which I am wintering in cellars. I have also bought 100 swarms this fall; and if they winter well I shall have something to do next summer, if the season is favorable.

Now, this may appear somewhat hap-hazard to you, but I assure you that I was not idle all the time, in looking up and attending to details, which are as essential in this as in other kinds of business.

So far my bees are not in debt to me; and should a sweeping loss come, it would not leave me worse than when I started. I am much indebted to GLEANINGS for many practical hints which I acted on, and to which I largely attribute my success, if it may so be termed. T. E. LOOPE, M. D.

Eureka, Wis., Jan. 6, 1885.

I am very glad indeed to get your report, doctor; but for all that, I think it a hazardous undertaking to start out in the way you did. Now I shall offer as a reason for your doing so well, that, in the first place, you are a doctor, and are presumed to be tolerably smart, with the advantage of a "physic education," as the old lady said; and on top of it all, I am sure you had two pretty favorable seasons. Wisconsin has been a little above the average during the year 1884, even

though some of the brethren do say, "Tain't so." I am glad that you had good luck in getting hired help. Do you know, doctor, that speaks well for you as well as for the help? One who finds good efficient people right around him is generally a good and efficient man himself. You say you were around attending to details considerable of the time, and the way it has turned out shows that you were. Attention to little details is oftentimes what makes the result a success or a failure.

THE PURPLE FIREWEED, OR EPILOBIUM ANGSTIFOLIUM.

ALSO CALLED WILLOW-HERB.

IN answer to our editorial in the January No., asking for seeds of the above plant, we have received a small package of the heads of the plants, with the well-known thistle-down blooms accompanying the seeds. Whether the seed will grow or not, I do not know; but we have given it a place in the greenhouse, and are watching anxiously. The letter below, from the friend who furnished the seeds, will give some light on the subject. As it is well known that fireweeds grow best where brush-heaps have been burned, our mailing-clerk asked if it would be necessary to burn down our greenhouse, in order to make the plants thrive. Our friend Lettie replies in the same strain.

Editor Gleanings:—Brother smiled a little when I bade him go forth and seek the seeds of the *Epilobium angustifolium*, but he went nevertheless, and as a result of his search I send you a little package by this mail. If it should prove to contain a few seeds that will grow, I shall be very glad; but it is my belief that dame Nature scattered all her fully ripened seeds last fall. I have no doubt the plant will take kindly to cultivation; but I should not expect it to thrive by scattering the seeds broadcast along the highways and in waste places. Hardier plants—grass and clover, and berry-bushes—easily crowd it out of the way. Of all places, it grows best in newly burned ground, so by all means "burn out the greenhouse;" for if there are any perfect seeds among these I send I should like them to have every advantage.

The common name, as given in Gray's Botany, and also in Wood's, is willow-herb. But it is often called fireweed—not unfrequently so in the bee journals, I believe. This is misleading, those not acquainted with the plant being in danger of confounding it with the true fireweed—*Erechtites hieracifolia*, a plant which blossoms later in the season, and yields honey of decidedly inferior quality.

The willow-herb and the *Gaura biennis* belong to the same order (*Onagraceae*), though not to the same genus. They are not sisters, but "cousins."

You must let me know if the seeds sent do not germinate, and another season they shall be gathered earlier. LETTIE A. WILKINS.

Mich., Jan. 7, 1885.

The two plants, although belonging to the same order, are so unlike in appearance, one would hardly be likely to call them even "cousins," if it were not for the botanics. I have never seen the willow-herb growing;

but if it bears honey any thing like the gaura, it will indeed be an acquisition. We are going to have a plat of them down on the rich creek-bottom land, if we can get the plants to growing nicely in the greenhouse. Now, if any other brothers or sisters can furnish seeds of either we shall be glad to hear from them.

REPORTS ENCOURAGING.

FROM 87 TO 127, AND 8000 LBS. OF HONEY.

I SEND you my report for 1884, this being my first season in the business. I procured 43 colonies of black bees during the summer of 1884, and 44 colonies last January, all in box hives. I lost one colony in wintering; transferred 12 in February to Simplicity hives, and had to run the rest in box hives. About 100 swarms came out. I crowded them into 36 hives. I saved every swarm that came out. I have 2 Italian and 4 hybrid colonies. I got about 3 tons of extracted honey, and one ton of comb honey in 2-lb. sections. I have it nearly all sold; got 10 cts. for extracted, and 12½ for comb honey. I have 127 colonies now. All of them have plenty of stores for winter, though a few are weak in bees. They are starved-out swarms that came to my apiary this fall. Bees commenced swarming about the 20th of March. The honey-flow commenced the 1st of May, and was over the 1st of June. We did not get any summer or fall crop, on account of the dry weather. My best hive made 240 lbs. of extracted honey. Some of my box hives made 125 lbs., about half comb. I did not have much comb foundation this season. If I could have had plenty of foundation and hives, my report would have been better. Most of the honey I got was gathered from cat-claw, and is very white and fine flavored. I don't think it can be excelled. We have some fine honey-plants here; most of them are not mentioned in any bee literature I have read.

D. M. EDWARDS, 86 127.

Uvalde, Texas, Dec. 11, 1884.

FROM 17 TO 47, AND 2500 LBS. OF HONEY.

I herewith send my report for 1884. The 26th of April I took 45 colonies from the cellar (having lost two in the cellar). About 25 were heavy, and the rest light. The prospect at that time was bright; but cold, wet, unfavorable weather then coming on, they began to dwindle; and in spite of all I could do, the middle of June found me with only 17 good colonies and 8 light ones. At that time they began to gain, although I did not get a new swarm until the 29th of July; and about that time the fun commenced. The 3d of August, three swarms came out. The 16th of August, the last (an after-swarm) issued. I then had 47 all told. From the middle of July until the middle of August I took off 5½ lbs. daily, Sundays excepted; and when a day was missed I would take off 100 lbs. next day. Not a heavy yield, perhaps, but a good even one. The honey was all choice—white and alsike clover, wild raspberry, and fireweed. I took the first premium at the North Aroostook and the Maine State Fairs on comb honey. The three swarms that came off the 3d of August I put on to wired fdn., with side boxes, and a half-story on top, containing 28 1-lb. sections. In just two weeks each swarm had filled its hive and the 44 one-pound sections. The second swarm, hived the 16th of August, filled 7 frames.

RASPBERRIES BY THE HUNDRED TONS.

The wild raspberry is a fine honey-plant, and is quite plentiful here. Last year the traders began to buy raspberries for the Boston market. At three of our villages they bought and shipped 94 tons. At the same villages this year they bought over 100 tons, and probably where one ton was picked, ten rotted on the ground.

As the result of my little apiary this year I got nearly 2500 1-lb sections filled; 600 lbs. of extracted honey, and most of my hives (the Simplicity) have now ten frames each. Had I not been very busy, I should have taken out spare combs, and extracted 500 or 600 lbs. more. When the prospect looks the brightest, we often fail of getting honey; and when it looks dark, a favorable turn of the weather will give us a good crop of surplus honey. It seems that a bee-keeper should always be prepared. This has been my experience.

E. TARR.

Castle Hill, Maine, Dec. 22, 1884.

FROM 37 TO 61, AND 800 LBS. OF HONEY.

I commenced with 37 colonies; have sold bees and queens enough, perhaps, to pay for the care of them during the summer. I now have 60 (several are nuclei); have taken about 800 lbs. of honey, 400 lbs. comb, and 400 extracted, comb is ready sale at 12½ cts. per lb.; extracted, 10 cts. per lb. I used a few of the 1-lb. section boxes as directed in A B C book, and am much pleased with the result. My bees worked in them readily. Queens never troubled the boxes. Owing to the short crop of honey the past season I got only about 100 well-filled sections, but they were very nice. The queen which I bought of you last fall did me good service during the summer, and is all right yet. You wish to know how the dies (which I bought of D. S. Given) answered for making fdn. By pressing half sheets I could make good fdn., but could not press whole ones, for want of power. The bees accept it, and draw it out readily. I am now of the opinion that it would have been cheaper to have bought foundation, all things considered.

My report is not so encouraging as some I see in GLEANINGS; but, please do not put me in Blasted Hopes yet, for I am not discouraged; I have just planted my vines for a grapevine apiary.

W. D. THARP.

Williamsburgh, N. C., Dec. 25, 1884.

PRETTY WELL DONE FOR AN A B C SCHOLAR.

As others are sending in their reports for the past season, I thought I would send in mine. My report for 1883 was very discouraging, but I was not ready for Blasted Hopes. I cherished a faint hope that I would have better success this year, and I have not been disappointed. I commenced the season with 15 colonies—9 strong and 6 weak. Fed about 75 lbs. of sugar. The spring was very wet and cold up to about the middle of May; just honey enough for brood-rearing. I increased to 30 colonies, but lost two from moths, and three by robbing, and doubled up two, leaving me 24 colonies. Found a tree in the woods; saved the bees nicely, thus making 25, all in good condition for winter. Now for the cash profits. I ran for extracted honey alone, taking 1700 lbs. of honey. Sold \$116.00 worth at from 10 to 12½ cts. per lb., and stored away between 450 and 500 lbs. for home use. I am not good authority in such matters; but I think I have done very well for an A B C scholar. I also made a regular hand on the farm, and with the

help of my boys, made 750 bushels of corn, 18 tons of fine millet hay, and 10 bales of cotton, and five tons of cotton seed. Since reading your article on page 789, Nov. No. GLEANINGS, on carp-ponds, I have thought a good deal about carp-raising in connection with bee culture; but I am somewhat doubtful as to success in this section, for there are no running streams in this portion of the country. We construct artificial ponds, or tanks, as we call them here, by levees across ravines. Such ponds fill up during the rainy season; but the trouble is, during the long droughts the ponds get very low and muddy; though common fish live and do well as long as there is any water in the pond. Perhaps some of the readers of GLEANINGS can tell us whether carp will do well in small tanks. S. F. DELLIS.

Hubbard City, Texas, Dec. 27, 1884.

MRS. HUNTER'S SUCCESS IN MICHIGAN.

In the spring of 1879 I bought my first swarm of bees. Have sold in all, since then, 2500 lbs. comb honey, at an average of 14 cts.,—\$350; 260 lbs. extracted at 10 cts., \$20. Have received for taking care of bees for neighbors, \$30; I sold 23 swarms without hives, at an average of \$5, \$100.00; have on hand 20 good swarms, with hives, racks, sections, comb fdn., etc., enough for another season, all of which I value at \$200, making a total of \$700.00.

Paid for the first swarm, and since, as needed, for hives, fixtures, sections, comb fdn., queens, extractor, winter-boxes, and help to pack them in chaff for winter, \$100, leaving a net profit of \$600.00. I have never fed sugar, but have fed honey; perhaps that accounts for the small amount sold. I have tried to prevent swarming, and have never lost a swarm by wintering or disease.

MRS. MARY HUNTER.

Vicksburg, Mich., Dec. 29, 1884.

FROM 133 TO 190, AND 12,000 LBS. OF HONEY.

We inclose the following as our report for 1884: March, 1884, 153 colonies; Nov., 190 colonies; extracted honey, 12,000 lbs. We had a very unfavorable spring, though a great amount of bloom. The weather was too cold and wet. Our honey was gathered in May and June, from horsemint bloom, and in July from the mesquite bloom. The mesquite yields fine honey, and the yield from that source this year is the best I have ever seen. In consequence of the scarcity of money, sales are slow, notwithstanding honey is now the cheapest food that can be bought here. Our honey here is always of fine quality. We use the Simplicity hive and the "tiering-up" system. Our bees are Italian, native, and hybrid. The Italians have this year shown great superiority over the native brown bees. Our only "winter trouble" here is to keep down robbing, and supply food if needed. For the latter purpose we keep combs of sealed honey. No frost yet, and bees carrying in pollen. Plenty of drones yet. In consequence of the drought (no rain since the 28th of May), our bees have gathered no honey since July. I should state, that the mesquite glories in dry weather.

W. A. MCPHAIL.

Gallinas, Texas, Nov., 1884.

FROM 70 TO 155, AND 800 LBS. OF HONEY.

Bees have done well this year, took more than 8000 lbs., nearly all extracted, from 70 colonies, spring count, and increased to 155 colonies; the honey is first quality; no basswood this year.

Mining, Ont., Dec. 19, 1884. S. H. KERFOOT.

FROM 60 TO 80, AND 4000 LBS. OF HONEY.

I am a beginner in the bee business. I began with 60 swarms last spring; that number is now increased to 80, with a surplus of 4000 lbs. of good pure honey.

GEO. HOAR.

Maple Landing, Iowa, Dec. 31, 1884.

ANOTHER "STUNNER" FROM CALIFORNIA.

We have 722 stands of bees, all in L. hives, and 46,000 lbs. of honey. My partner and myself, with the assistance of our wives, extracted in one day in July, 4500 lbs. of honey with an 8-frame extractor. My friend and neighbor, Mr. R. Wilkin, has gone east to try to sell his 50 tons of honey.

Ventura, Cal., Dec. 15, 1884.

L. E. MERCER.

REPORTS DISCOURAGING.

\$12.00 IN FOR HONEY, AND \$45.00 OUT FOR SUGAR.

BEEES did very poorly here this year. I got only \$12.00 worth of honey this whole year, and I fed \$45.00 worth of sugar—nearly 700 lbs. How is that for profit? I thought I should make something out of my bees this season, but I worked hard all summer and got nothing but bees. I increased from 38 to 82; and when I had to go to feeding I united them down to 68. I think they will go through the winter all right, if it is not too long.

MALINDA A. WILKINS.

Seneca, Kan., Dec. 23, 1884.

REPORT FROM A BOX-HIVE MAN.

I live in Belmont Co., O. Last spring I bought of you 20 or 25 dollars' worth of Simplicity hives. I got to use only one, as my bees did not swarm. I wintered 15 colonies last winter. None of my hives have movable frames. I simply have boxes in upper hive for surplus honey. My 15 colonies made about 200 lbs. of surplus last summer, and one swarm of bees. Last season was too dry for bees. I took a box of honey the other day that was probably made from tobacco-blossoms. There were four or five acres of tobacco on the place. The boys said the bees worked on the tobacco last fall lively. The honey I spoke of is very peculiar. It is not good. I sold a few boxes of good honey the other day for 12½ cents a pound. There are but few bees in this neighborhood. Honey is mostly made from white clover and poplar and linn.

ERASTUS MOORE.

Beallsville, O., Dec. 23, 1884.

THIEVES IN THE APIARY.

I think you will have to put my name in Reports Discouraging. I lost 25 colonies during the winter of 1883, commencing the season of 1884 with 11 small colonies. I increased to 27, but reduced to 21 for winter; made about 25 lbs. of beeswax, and about 2½ lbs. of comb honey. Nov. 3, in order to put the cap on the rest, some generous brother stole the very best colony (the only one that had made any section honey), cut out the honey, and left the hive and bees on the ground. My wife and I picked up the bees, and thawed them out; and as we could not find the queen, we united them with another colony. Bees are all right at date; have all in chaff hives; fed 75 lbs. of granulated sugar. I am not discouraged, but hope to do better next time. The spider plant did well. The bees worked on that when they could not get much else.

WM. COOK.

Watervliet, Mich., Jan. 5, 1885.

OVERPRODUCTION OF HONEY.

FRIEND POND GIVES US SOME THOUGHTS IN REGARD TO THE SUBJECT.

FRRIEND DOOLITTLE criticises me a little on page 700, Oct. GLEANINGS, as regards my views on overproduction. Well, I don't intend to take back any thing I have ever written in regard to the matter, and I still think the questions of overstocking or overproduction are matters which need not trouble this generation, and that the price of nice honey is no lower than years ago. True it is, as friend D. shows, the price of honey is some ten cents per lb. lower this year than it was some ten years ago; so is flour much lower in proportion than it was then, as compared with the reduced price of honey; and so goods of all kinds are lower also. When I mentioned the price of honey it was comparatively. I meant to be understood relatively also; and now when I compare the present price of honey with the necessities of life, I find the argument strongly in favor of honey.

Now, the real question of supply and demand does not govern the honey question at all. Producers of honey are not salesmen, and consequently have no real knowledge of the best ways and means of disposing of their goods. Instead of making a market for their surplus honey, and disposing of it in that market, they all rush it into some large city, and, of course, overstock that market at once. Compare for a moment the crop of honey of the last ten years with the number of people in this great country, and how much per capita will it show up? There are thousands and thousands of people who would gladly buy honey, if they could do so near their homes, who never see an ounce from one year's end to another. So I say again, this generation has no reason to worry itself about the matter of overproduction of honey, or overstocking the country with bees; and further, the crop of honey as compared with the necessities of life commands as good a price now as it did years ago; and the price obtained for it might be largely increased if the bee-keepers would market their goods themselves, and not ship it all to the same central point, and leave the disposing of it to the tender mercies of the commission houses. J. E. POND, JR.

Foxboro, Mass., Dec. 21, 1884.

EMPTY COMBS AND COMB HONEY.

SECTIONS FILLED WITH FDN., AND EMPTY FRAMES BELOW THEM, FOR NEW SWARMS.

FRRIEND W. Z. Hutchinson's article on page 803 of GLEANINGS for 1884, upon "foundation and comb honey," was read by me with great interest; for it touched upon some points of vital importance to the bee-keeping fraternity.

While in the main I consider his conclusions correct, yet I think some of them need a little explanation before the apiarists of the United States will indorse all that he says; and the object of this article will be to throw more light on the interesting subject of comb-building, and to tell why friend H. did not succeed in securing a good yield of comb honey from those swarms which were hived on empty combs. In order to have what I wish to say more fully understood, I will begin at the close of friend H.'s article, and explain it toward the beginning. Thus we have first, "When the young queens began

laying in the old colony, they shunned the frames of drone-comb, even if they were in the center of the hive." Here we have an assertion, with no reason given to support it; and so I ask, "Why was this so?" Because, when an old colony gets a young laying queen, instinct teaches them that they may expect this queen to meet all their requirements of a mother-bee for the rest of the season; while drones are necessary only when a change of mothers is contemplated by the bees. Hence no eggs are deposited in drone-comb, and no drone-comb built by such a colony, unless such comb is built for store comb where honey is coming in rapidly. Taking advantage of this fact or explanation, I manage to get one or two nice perfect worker-combs built for future use while the bees are at work vigorously in the sections, by taking one or two full combs out of the center of the brood-nest, and inserting empty frames in their places. These frames are filled, apparently, without the cost of any section honey, while it gives that energy to the colony which friend Root speaks of, as always accompanying a colony which are building natural comb. In this way a part of the combs which I use are built, which combs are given in preceding years to newly hived colonies, as will be explained further along. I also place on such colonies having young queens, all sections (if I have such) containing drone-comb, where they are filled without danger of drone-brood in them, while much drone-brood in sections often confronts the apiarist, if such sections are used over prime swarms. Before I used this plan, and previous to the advent of thin foundation for sections, I was often vexed upon finding the sections placed upon prime swarms, nearly half filled with drone-brood. In the above I have given how I get nice worker-combs built without cost, and also how to keep brood out of sections, which is done by using all sections containing drone-comb over an old colony having a young laying queen, and having only sections of worker-comb over all colonies having a queen a year or more old.

The next point I wish to notice is where friend H. says, "With me, newly hived swarms having laying queens do not build drone-comb." Here we have another assertion (without reason given telling why) which is contrary to the experience of nearly every person who ever hived a swarm of bees. Only the past season I have seen, in neighboring apiaries, hives filled nearly half full of drone-comb when laying queens went out and were hived with new swarms, and why they did not do so with friend H. was simply because his bees were managed differently, and upon a more correct principle. The colonies above alluded to were hived in a hive containing 12 Gallip frames, with no surplus arrangement put on until a week after hiving, so that it was necessary that the bees do all their work in the body of the hive. All observing apiarists know that, as the day of swarming draws near, the queen ceases her prolificness, so as to be able to fly and go with the swarm, so that, when swarming does occur, said queen is scarcely larger than a virgin queen. Nature has so ordained things for two reasons; the first of which is, that the queen can fly; and the second is, that the queen need not be damaged by an over-accumulation of eggs before there is time for the bees to construct comb in the new home for her to deposit her eggs in; thus we find that all good queens do not get fully prolific again until about a week has elapsed after the new

colony has arrived at its new location. During this week, comb has been built very rapidly, especially if honey is coming in plentifully from the fields, while the queen has not been able to keep up with the workers; the result of which is, that the bees commence to build store comb, which is always of the drone size of cells. This comb is mainly filled with honey the first season (although in some cases some drone-brood is found in them, especially if the bees feel disposed to supersede the queen or the honey-flow slacken somewhat), while the main trouble comes in having this store comb filled with drones after the bees have consumed the honey out of it the next spring. In the above I have given the "why" bees build drone-comb for the majority of bee-keepers, and now why do they not do so for H.? Simply because he put those sections filled with comb foundation on the hives at the time of hiving the swarm. This gave the bees plenty of room above for store room, so that only comb of the worker size was built below, and that only as fast as the prolificness of the queen demanded it. As her ability for laying increased, more comb was built, till at the end of the season friend H. had his hive filled with nice worker-comb and lots of section honey. Hence it all came from putting on those sections at once instead of waiting, as others do, thus securing three things, lots of section honey, no drone-comb, and a hive full of nice straight worker-comb, the latter costing almost nothing. Friend Root seems to attribute the success to the Heddon arrangement; but I think that has little if any thing to do with it, as I have used the plan successfully for years, and gave it once or twice several years ago in the bee-papers.

Well, I have already written enough for an article, and have not yet reached the main point in H.'s article I set out for; so, with the permission of the editor, I will say, concluded in next number.

G. M. DOOLITTLE.

Borodino, N. Y., Jan. 1, 1885.

By all means, friend D., give us the remainder of this interesting subject. It is just now one of the greatest importance to all concerned in the production of comb honey.

FRIEND DYKE'S BEE-FEEDER, AND SOME OTHER MATTERS.

INTRODUCING QUEENS, UNITING NUCLEI, BEE-STINGS, ETC.

AS I have not had a hearing in GLEANINGS since the great flood of Feb., 1884, I again offer a "few remarks." I notice in last GLEANINGS, that friend Heddon describes a new feeder. Now, I was very much surprised to see how much it is like a feeder I got up and used last fall for the first time, and also pleased to find that great minds run in parallel channels. The difference between my feeder and Mr. Heddon's is, first, mine is to be set inside the upper story on the frames; 2, The bees come up at one end instead of on the side; and thirdly, the feeder is covered with a loose wire-cloth top. The construction of the feeder is as follows: I first made a box 12 by 16 inches inside, 5 inches deep, with a partition one inch from one end open at bottom for passageway for bees. I used stuff $\frac{1}{2}$ inch thick. This box was thoroughly smeared with wax inside, to avoid leakage. In the partition, and opposite end, verti-

cal slots were cut, $\frac{3}{4}$ inch apart from center to center, $\frac{1}{2}$ inch wide, to slip thin boards in, similar to his feeder, which gives the bees feeding-ground, as it were. Those thin boards were $4\frac{1}{4}$ inches wide, and were prevented from going to the bottom of the feeder by a 5-16-square strip, long enough to reach across each end of feeder. The partition came within $\frac{3}{8}$ in. of top of feeder. For the cover I made a wooden rim of strips, 1 by $\frac{3}{8}$ inch, just large enough to fit over outside of feeder; upon this I tacked a wire-cloth top, so by placing it on feeder it was all closed up, except opening at bottom. Now to use this feeder I simply turned one corner of mat back far enough to make an opening corresponding with the hole in bottom of feeder. Press the mat down flat so it will stay, then set the feeder down close up to the corner of hive, so that the openings will be together. Now all you have to do is to pour in the feed right through the wire-cloth cover. It will run through without any trouble. The next time you want to fill it you can take out every bee, if you are afraid of drowning them; but I always pour the feed in, and the bees soon came up and went into the hive, not seeming to be injured by their impromptu bath. I examined a feeder which I used all last fall, and there were not half a dozen dead bees in it, and it never leaked a drop.

I do not want to appear presumptuous, but I believe I like my feeder better than Mr. Heddon's, as I fear that there would be too many chances for robbing, unless those covers were fitted nicely; and even after we are careful to have such things to fit well, the sun and rain play havoc with our calculations. The feeder which I have described holds about $1\frac{1}{2}$ gallons of syrup, which is generally enough for one colony, unless they are unusually destitute. To any one inquiring about the manufacture of this feeder, I would say that I will advertise them when I am ready to furnish them.

UNITING NUCLEI.

I read with much interest friend Doolittle's method of uniting nuclei. As your readers are doubtless aware, I raised many queens last year, and consequently had quite a number of nuclei to unite in the fall. I remember in one case I made one colony of 6 nuclei. I took the queen I wished to keep, put her in a cage, and removed all others. I then took a chaff hive and put in one frame from each nucleus, taking only such as had the most honey (there was not much brood). I then filled the remaining space with four of my best frames, after which I brushed all the remaining bees from the frames and inside of nucleus hives into the top story of hive. After smoking them down and covering with mat, they were smoked at the entrance, and a strip of wire cloth tacked over the same. This was done just at evening. They were given plenty of ventilation, and left until about four o'clock next evening, when they were liberated, after which all went well, and not a bee seemed to want to go back to its old stand. Some of my now best colonies were thus treated. I forgot to say that the queen was placed in an introducing-cage, and the bees allowed to let her out at their leisure. This brings me to another topic; namely,—

INTRODUCING QUEENS.

Some months ago friend Doolittle gave us an article on this subject, and I remember that many of his ideas were good; and especially one which was, to liberate the queen just at night, by means of a

string attached to the lid of the cage. I have been advertising an introducing-cage during the past year through GLEANINGS, which, I think, carries out this point of Mr. Doolittle's, in a special manner; and the means of accomplishing the result are under the control of the bees themselves. It has been my experience thus far, that a queen is very seldom, or never, lost if liberated during the night, if they have had sufficient time to become acquainted before being liberated. I do not undertake to explain this peculiarity; but I have noticed that, when different swarms of bees are united just at nightfall, they are much more peaceable, and less apt to fight. When we become convinced of any such disposition on the part of our pets which we can use to our advantage as well as theirs, we should be quick to avail ourselves of it, and not stand back and pooh-pooh at it as a notion.

BEE-STINGS.

Much has been said of late regarding severe bee-stings. I had a slight experience that has taught me one lesson at least, which is, to have a bee-veil handy when working with especially cross bees. I bought two colonies of bees last spring in American hives—one Italian and the other hybrid. Well, as I use the Langstroth hive exclusively, they must be transferred, as a matter of course. So one afternoon in May, during fruit-bloom, I proceeded. I left the hive on its stand, and took out the frames one by one, and carried them two or three rods to the new hive, where I shook off the bees and transferred the combs. I had gotten about half way through the first (or hybrid) swarm, when in lifting a frame from the middle of the old hive, the bees with one accord raised and covered my face, head, and arms, stinging me most severely. My wife had the smoker, and I called her to smoke them off me as I held the frame in my hands, and was wholly at their mercy. She somewhat timidly came up and helped me a little, but I had to put down the frame as soon as I got to the new hive with it, and defend myself as best I could. I finally subdued them, and finished transferring. There was but one sting in all I received (which were many) that gave me any trouble, and that was a sting on the upper lid of my left eye. It swelled somewhat that night, but did no special harm until about 10 o'clock the next forenoon, when it commenced bothering me, and I thought there was something in my eye, and tried to rub it out; but my rubbing caused it to commence inflaming to a rapid degree, and it was but a few minutes before I was obliged to quit my work and walk half a mile home, which I did under the greatest difficulty, as my eye was so inflamed that I was almost blind (my right eye has been useless since I was fifteen years of age). All I could get to help me was to lie down and apply cloths wet in cold water, changing them often. It was more than two weeks before I could do much work, as the inflammation made my eye very weak, and it was quite a while before I got rid of a kind of blur before my vision. I supposed, at first, that the sting had worked clear through the membrane of the lid, and I had a doctor to examine it, but he claimed that such was not the case, and that it would be impossible for such a thing to happen. Be that as it may, I have had my fill of that kind of stinging, and I advise people who have weak eyes, or only one, to use a veil, as you can not tell when you may get a sting that may lay you up for weeks.

Pomeroy, O., Dec. 30, 1884.

S. A. DYKE.

I would suggest, friend D., that the reason why uniting and introducing are better done at nightfall is, that all annoyance from robbers is effectually cut off until the bees can have time to settle down quietly. Through the daytime, sentinels are obliged to keep a lookout for robbers, strangers, or intruders; and at such time a strange queen or strange bees would come under the head of intruders; whereas, after bees have stopped flying, no guard needs to be kept at the entrance, and the bees, as it were, are not on the defensive, as they are during the daytime.

PURE GERMAN CARP.

A FISH 35 INCHES LONG, AND WEIGHING 14 LBS., AMERICAN RAISED.

FRIEND ROOT:—As the carp is almost the absorbing question at this time, and seeing that you and a great many others are interested in their culture, I will give you my experience.

In reading the *American Agriculturist*, of Jan., 1880, I found a description of the carp as given by Prof. Baird, U. S. Fish Commissioner at Washington, D. C., whereupon I made application, and in due time secured 20, averaging about 4 inches long, of the three varieties; viz., leather, mirror, and scale carp. This was in the fall of 1880, which will make my largest carp about five years old this spring. Now, you see I received them from the first general distribution made by the government, through Professor Baird; and if there are any pure German carp distributed by him, I have them.

My largest carp is about 35 inches long, and weighs about 14 lbs., and I have from that size down to 3 inches. This large one I speak of is a "Mirror," and has scales larger than a 25-cent piece. My pond is the first one built in this section of the country, about 70 feet wide and 140 feet long; when full, about 7 feet of water at deepest point. It is built on the south-east side of a considerable slope, lying fair to the sun, which I think very essential to both hatching and growth. I have it arranged so that all the surface water passes around the pond.

You spoke in the Dec. No. of GLEANINGS in reference to instructions on pond-building and carp culture, for sale at one dollar. I will say to all, that on receipt of a stamp I will give all instructions needful, free of charge, and I have had as much successful experience as any one in the country. There is no mistake; the culture of carp is a success. It is of all fish the most readily propagated and reared. The will become tame, and eat from the hands of their keeper. Their fecundity is great. A fish weighing 4 or 5 lbs. will lay 400,000 to 500,000 eggs, and one of 10 or 15 lbs., 1,500,000. They spawn from May to September. Their diet is largely vegetable; they are not carnivorous, and should not be in ponds with other kinds of fish. They will live in water where all other fish will perish; for instance, in pools, tanks, bog meadows or sloughs, as well as in lakes, rivers, or streams. They go down in the winter, and "kettle" in squads of from 50 to 100, and stay in a torpid state without food until warm weather approaches.

Their growth is very rapid, making from 1 to 3 lbs. in one summer. That depends on condition of water, and the amount of feed. They will eat almost any thing. I have fed raw corn, cabbage, corn

meal, cooked sweet and Irish potatoes, bread, meat, —in fact, all refuse of the table. Last summer I bought stale crackers, and fed my young carp, and found it a good investment.

All ponds want to be kept opened in winter, in order to give the fish air. My friend Mr. Walker, of this place, lost all his carp, save twelve, by his pond freezing over last winter. I am often asked, "Will they bite a hook?" I think, friend R., if you had seen me throwing them out last summer you would have thought so. It's the finest sport in the world, no mistake. It is the cheapest and best meat grown.

W. S. KALER.

Andersonville, Ind., Dec. 25, 1884.

Friend K., you have given us some very valuable facts indeed: but the most important to me just now is, how many fish do you keep in a pond of the dimensions you give? Not many, a yard long (or pretty nearly that), I should say. Where land is valuable, it is a question as to how large the ponds need to be. Yours is not very much larger than our own: but I am told that 100 five-pound fishes would overstock our pond. Perhaps abundant feeding would remedy this. Can you tell us about it? In regard to directions for constructing ponds, instead of mailing them singly to all who are interested, why not let us have the matter and have it published? I will pay you for it; and if there is not room enough in GLEANINGS, we will add some additional pages.

MY FIRST REPORT.

SOMETHING FROM A CALIFORNIA A B C SCHOLAR.

STARTED in last spring with one swarm that we had had for two years, and never got anything from. I didn't know any thing about bees, so I lost a lot of honey, I'm sure. Well, when the bees began to swarm I began to get interested. Though not knowing how important it was to have them in movable-frame hives, I put the first nine swarms in box hives, which I haven't got a thing from, except some more swarms. After this we got seven more swarms, one of which we bought, and put all these into good frame hives. From the seven last swarms (some of which came out as late as August) I got 90 lbs. of comb and 220 lbs. of extracted honey, and 3 of wax, which I think is a pretty good show for such late swarms. Now, how much would I have got from the eight early swarms and the old stand, if I had put them all in good frame hives?

There is a great deal of comb honey yet in the nine box hives, but I am waiting till I transfer them, to take it out. They are all "plum full," and some of them are very large boxes. I am waiting till fruit-bloom begins, to transfer them, and then I suppose I shall have a practical lesson on the folly of putting swarms into box hives, by the trouble they will give me. About five of the swarms we got were traveling across the country, and were attracted to our bees, and settled near them, and we caught them. Runaway swarms have to travel a long way across the country here before they find a resting-place, as there are no woods or hollow trees for them to get into, so they just have to go till they get into some crack in the roof of a house, or some one hives them. We have two such swarms in our house, where we can't get at them. They were too

sharp for us, and got into the cracks before we could hive them. Now, if my report is too long, just cut it short here and there. I am an A B C for the last 6 months only.

ALFRED W. HIND.

Anaheim, Cal.

Why, friend H., how many swarms did you get from that first one you started with, pray tell? Your letter reads as if you built up that big apiary from that one colony in the spring. You say further along, however, about five of those swarms were traveling swarms. May be that accounts for it. You do not tell us, either, how many you have now, but I should think California must be a pretty big place to keep bees.

HOW A DISABLED SOLDIER SUCCEEDS IN BEE-KEEPING.

A HOME-MADE FOOT-POWER SAW.

THIS has been the hardest season on bees and bee-keepers for many years. Great numbers of colonies are starving to death now, simply because their owners were too careless or too stingy to give them the food that they could not get for themselves. I had the care of about 20 colonies. Some belonged to my neighbor. I transferred the most of them during fruit-bloom, and from the 20 colonies, not a single swarm issued. I took no precautions whatever to prevent swarming, only giving room in surplus department, while about all of my neighbors who use the old box hives got from one to four swarms to the colony; but I think it my turn to smile as their little colonies are now swarming out, and starving, while my hives are full of bees and honey, and in good trim for a long winter sleep.

I was not able to buy an extractor, consequently got but little honey; a few colonies give 50 lbs. in 1-lb. sections, while others, apparently just as strong, gave no surplus at all. Now, I suppose I am making a contribution to your waste-basket; but I will have my letter so large that it will not slip through the "holes in the basket" that I was reading about in "hints" in GLEANINGS to-day.

I have finally got my foot-power saw completed. I ordered the saws, mandrel, belt, and files from your house; they all give splendid satisfaction, except the belt; it was too good, and I took it to the harness-maker and had it trimmed down about one-half, and now it is all right. I should like to tell you how I operate my machine with two blocks of wood and two straps, and get up a rate of speed that makes my neighbors almost fear to come in the shop; but you, I fear, would think I was exaggerating. I commenced early New Year's morning, full bent on making a Simplicity hive, as per instructions in the A B C, and I succeeded admirably until I came to take off the strip that goes under the cover, then I found that my 6-inch saw set close to a 2-inch pulley would cut only a little over 1½ inches deep; but in order to get my hive made, I sized the lumber to 11½ inches which worked all right, only it leaves the lid ½ inch shallower than it should be. I believe that, even with my disabled limbs, I can cut out two complete 2-story hives in a day, and that, in comparison to last season's slow work by hand, and the assurance that every hive I can possibly make is just as good as the cash, is very cheering indeed to a poor and disabled soldier, and I shall always feel indebted to you, friend Root, for the good and practical instructions I have gained from your writings.

A. B. HERMAN.

Burnettville, Ind., Jan. 3, 1885.

He that is faithful in that which is least, is faithful also in much.—LUKE 16-10.

MYSELF AND MY NEIGHBORS.

Well done, thou good and faithful servant.—
MATT. 25: 21.

I WANT to repeat a little sketch I saw in the *Sunday-School Times*. A little boy was doing something that he ought not to do. As he was only two and a half years old, he could not be expected to know very well what was proper and what was not proper. And besides, boys of that age are not always as obedient as we should expect them to be when a little older. His father stopped him by saying, "No, my son, you must not do that." It happened to be something, however, which the boy very much wanted to do, and for a while he seemed to question what the consequences would be if he did not mind. Finally his better self triumphed, and he replied, "All right papa, I won't do it any more." I presume most of us would think that was all there was to be said about it, and so the father thought; but the boy evidently had different ideas; for pretty soon he spoke out, "Pa, why didn't you tell me, 'That's a good boy?'"

Now, my friends, was not the boy right about it? When he had controlled the wrong impulse, and had triumphed over inclination, ruling his own spirit, as it were, would it not have been a wise thing for the father to have given him a little commendation? Would it not have been well, in fact, had the father watched the boy's face, that he might know the conflict going on within? What father or mother can not read their own child's thoughts, if they watch the face

and the actions? A little word of approval clinches the nail, as it were, and strengthens the child's purpose to do good instead of evil. It is not only among children and grown-up people that we notice this, but it seems as if the rule held good all through animated creation. My earliest recollections are connected with the business my father followed at the time. He used to carry the stoneware manufactured in our native town to distant towns around. For the purpose he had a large heavy wagon with a high top box, and two great stout horses; and in pleasant weather a smaller wagon with one horse followed behind, with my brother for a driver. When I became old enough I was allowed to take a trip or two; and, wasn't I proud, though, when intrusted with a whole wagonload of valuable property, and instructed in the mysteries of driving, so as to avoid rough places in the road, that my cargo might not be cracked and broken when it arrived at the destination? Well, when we came to long hard hills, father told me to let my wagon stand, and come with him and he would show me how. As the load was heavy, the horses were allowed a breathing-spell one or more times on the way up. Before we started up the hill he selected a suitable chunk of wood with which to block the wheels, which block he held in his hand as he walked along on foot. Before he started he patted the horses on their necks, and they glanced at the big hill, and seemed to take in what was to be done. When he gave the word, up they went with a will; but when the breathing became pretty hard, he would slack them up a little, and let the

wagon back against the block, until they had recovered their breath, and then on they went. Now, the point is here: After having pulled well, he always patted them, rubbed their noses, and told them they were good fellows. Sometimes they seemed so well pleased at this little praise that they would hardly wait until they were sufficiently rested, seeming anxious to get at it again, and show him how stout they were, and how well they could do. Faithful old Jake and Doll! Their tasks have been finished, and they are doubtless gone the way of all horses; but I remember vividly how much they appreciated a good word; and I know, too, how sullen and unhappy they looked when they were scolded. They did not often get scolded when at their regular business of drawing stoneware; but sometimes when they were called upon to plow the garden, or something like that, when they either did not understand or acted awkward. Did you ever know anybody who got out of patience plowing a small garden?

Now, boys and girls, men and women, is it not possible that *your* horses are hungry for a kind word or a word of praise? When your child or brother or sister has striven nobly against temptation, have you always been ready with the very important "That's a good boy"? or, "I thank you"? or whatever little praise would be fit under the circumstances? We complain when things are poorly done; but, do we make use of that other powerful lever in encouraging good resolves and good intentions—a kind and encouraging word? The baby of the household generally gets praises enough. I have sometimes thought it was almost as necessary to their growth and development as the milk they drink; and if kind words that spring from loving hearts are good for the babies and the horses, are they not good for older people? Some of you are children I am talking to. Are you always ready to say, "Thank you," "I am very much obliged indeed," and such like phrases? Sometimes actions speak louder than words, you know, and we ought to act pleased. Should we act pleased when we do not feel pleased? I want you to be honest, my little friends; but a great many times you *will* feel pleased just by trying. It is always right to do what you know you ought to do, whether you feel like it or not; and it is right to pat your old horse on the neck, and tell him he is a good fellow, even if you feel cross and contrary, and don't feel like it. Try it, and see if there is not something in your own hearts that pretty soon speaks to you, saying, "Well done, thou good and faithful servant."

Right here, friends, comes in the importance of daily thanks to God. One who thanks God for his daily bread, for the air he breathes, and for the gift of life, is a happier man than one who goes through life without giving thanks anywhere, or to anybody. And this daily thanksgiving should be followed up, even if you do not feel like it. I do not mean you should be a hypocrite; but I mean, as I said before, you should do your duty, whether your *feelings* prompt it or not; and your first and greatest

duty in this world is thanksgiving to God; and the next, thanks to your fellow-men. Of course, you need not be always saying to everybody the stereotyped words, "I thank you;" but by your actions, and these nameless little courtesies, show everybody that you feel pleasantly and kindly toward them, and carry this spirit and this feeling out among the cattle and the horses, and let it shine wherever you go. As I write these words, the feeling comes over me, "May God forgive me for having so many times in life been remiss in just this little thing. Help me, dear Savior; help me to practice that which I am trying to teach, here this bright January morning."

A LETTER FROM A BOY BEE-KEEPER.

ONE WHO IS OBLIGED TO GO ON CRUTCHES, BUT WHO SUCCEEDS PRETTY WELL NEVERTHELESS.

I WROTE you a business letter last summer; and as you published a scrap of it as news, and then in the last No. of GLEANINGS published my name on your list of correspondents, I will venture to tell you what I have done and what I hope to do. I am a crippled boy, 16 years old, and have to go on crutches, and therefore can not do so well as I think I could if I could get around better.

I bought two colonies of hybrids last spring—one in a Langstroth and the other in a chaff hive, something like the American. On the 24th of May, the Langstroth, being about to swarm, I divided them; and June 15 I divided the chaff hive. I think I made a mistake right here by losing much valuable time in brood-rearing. The way I divided was to take the queen and one frame of brood, and put in a new hive, and set it where the old hive stood, so as to get the bees that were out gathering honey. In the latter part of August the hive I divided first sent out a large swarm; and, not having any hive ready, I nailed three frames together and filled them with foundation, and hived the bees in a box about 12 inches square; and afterward I put in 4 more frames. I commenced feeding them from the time they swarmed, and kept it up as long as the weather would permit. I think they stored some honey, enough to carry them through.

In the latter part of July I received from you a select tested queen and 1 lb. of bees, which seem to have done pretty well. This makes 6 swarms, which I now have, and which I put into winter quarters in the cellar about the 1st of December. I also found a colony of blacks in a tree, which I mean to try to save. I took from the old hives about 25 lbs. of honey. I do not think we have the best country in the world for honey-producing plants. Orchards are somewhat numerous; there is but little bass-wood, and not very much white clover; there is considerable red clover, and my bees worked on it a good deal. There is also buck-berry and catnip, quite abundant. I found growing wild quite a number of Simpson honey-plants and transplanted some of them near my bee-hives. They produced considerable nectar, but I never could get a bee to even smell of them. I had an acre of buckwheat sown, which I think helped my bees. I am going to have an acre of alsike sown in the spring, and will try to get the farmers to sow white clover in their pastures, and I think we can make this a pretty good

bee country after a while. You have discovered that my bees are in a badly mixed lot of hives, and I propose to transfer them in the spring and have them all alike. Now, this is new business to me, and there are but few bee-men around here to show me much about it. I do not expect to get right into it without making some mistakes, but I am going to make it win if I can; and while I am keeping myself out of mischief, I want to make some money. I don't expect to beat pa with his short-horns, but I should like to come just as near it as possible.

Holton, Kan., Jan. 2, 1885. MARCUS BRYANT.

Marcus, I am very glad to see your zeal and courage; and if you go ahead as you seem to have started, I think there will be no trouble about your succeeding. Where there is a determination, and an earnest, go-ahead spirit, obstacles make but little difference. Of course, it is harder for you to get around; but it is better to be crippled in body than to be crippled by a lazy disposition. May be you may beat your father with his short-horns yet; who knows?—The bees failed to work on the Simpson plants, either because there was not enough of the plants, or because there were other sources of honey that were of more importance than these few plants you set out.

THE YOUNG PHILOSOPHER.

WHAT ANNA SAID, AND WHAT HER FATHER SAID.

I READ you would give a book to me if I would tell you something new and useful. I am going to try to get Ten Nights in a Bar-room. I asked papa to tell me something new. He said there was nothing new under the sun, for the Bible said so. Then I thought you would not have to give away many books. But papa said he guessed you meant things new to you. He said it would be new to you to find out I had 35 swarms of bees. But I said that would not be useful to you. He said it would, since he would buy books and goods of you, so I have told you something new and useful.

But I guess you will not think this is fair, so I will tell you about papa's "bee ring," as I call it. It is made by planting young cedars close together in such a way as to make a ring. Keep them trimmed well as they grow, and they will be very thick, so that the wind can not blow through them. Let them grow close to the ground, and little pigs can not get through them. Papa says a half-ring is better than a whole one. Take the north half, let the trees on the north grow eight feet high or more, but gradually lower them on each side till they are not more than two feet high where they end. Then it will look like a new moon, and no shade will ever fall on the hives, and it will be the warmest place that can be found out of doors in the winter, and yet quite cool enough in the summer. Of course, the bees should have shade in the summer. Papa says he likes raspberries better than grapevines for shade. On the south side of each hive, put two plants about two feet apart. Let them grow 30 inches high; keep the side limbs pinched off close to the stalks, except those between the two stalks; let those interlace till they make a thick shade.

The bees got lots of honey out of flowers, and we got a good crop of berries. Bees never bother ber-

ries as they do grapes. Every bee-man who sees papa's ring says he must have one.

ANNA ANDERSON, age 9.

Ladoga, Ind., Dec. 19, 1884.

Give my respects to your kind papa, friend Anna, and tell him that I think he has succeeded in furnishing us something both new and useful. In fact, the first paragraph of your letter is pretty sharp, both for you and your pa.—I think that cedar bee-ring would be beautiful; but the most interesting part of your letter is the raspberries for shade. They are more of a bee-plant than grapevines, and, come to think of it, I believe they would answer even better. Last fall I bought 500 strong pot-grown raspberry plants that are almost too large to go into pots now; besides, pots are too heavy for shipment. Some of the friends say they do not care for pot-grown plants. But I do. I would give more for one good strong plant growing nicely in a pot, than for half a dozen like those usually sent out. The pot-grown plant will keep right along growing, and bear a crop of fruit, at least a small one, this present year. Now, my neighbor is going to put 1000 of these strong raspberry plants in quart paper oyster-pails. The space around the plant is to be filled with nice compost, and when they get nicely to growing in the spring I am going to offer them for sale to plant around bee-hives for 5 cts. each. When any of you are ordering goods you can have one of my potted raspberry plants, oyster-pail and all, for an even 5 cts., if you want it. We shall have both the Gregg and Doolittle black-cap varieties of raspberries. Neighbor Green, who furnishes them, says they get more berries from the Doolittle black-cap than from any of the new-fangled kinds with high-sounding names.

WHAT SORT OF GLASSES DO YOU WEAR?

A WHOLESOME LESSON FOR OLD AS WELL AS YOUNG.

TWO little children, Tommie and Kitty, were amusing themselves one morning by looking through the colored glass panes on either side of the hall door of a house where I was visiting in St. Albans. The lower panes were of a bright crimson hue, the next of a deep blue, the others of yellow, green, etc. Little Kitty's small size permitted her to see through only the lower panes; and every object she looked at, trees, flowers, people, and even the ground, seemed to her eyes gloriously bright, almost as if on fire; not because they were really so, but because seen through the medium of the crimson glass. The little girl did not dream this was only a borrowed light, and she called out to her brother, "O Tommy! this yard looks the prettiest that you ever saw this morning. I do believe the trees and the flowers, and the ground too, are just going to burn up. Come, see how bright they be; they look like the fire up at Uncle Nat's, in the big fireplace."

"It is n't bright at all; it looks all blue, and just as gloomy looking as can be; and I guess it is a going to snow too," said master Tommy, who was some two years older than Kitty, and felt himself

quite too tall to stoop to the lower panes; so by dint of tiptoeing he was able to look through the second, or blue tier. The reflection of the blue glass gave to every object in view the somber tint of an approaching snowstorm, and eight-year-old Tommy wondered how his sister, looking out into the same yard, could see such brightness, while he saw only gloom.

During this conversation between the children, I sat by reading, book in hand; yet not reading, but thinking how prone we all are to judge of people and things by the sort of glass we look through, and how many kinds of glasses there are! There are the clear, transparent glasses of true faith; not only faith in God, that never stumbles at either his promises or providence, but faith in our fellow-men, hoping always and ever for the return of the prodigal, believing in his penitence, enduring patiently his stumbling, and halting and hesitating, and that buoys him up and enables the poor reprobate to overcome at last, because it will not see any good cause to be hopeless.

Opposed to these are the magnifying-glasses of presumptuous self-dependence, that paint one's own faults as virtues, see strength where there is only weakness, and mistakes conceit for wisdom. Then there are the green glasses of envy, that can never be turned toward a kindness done to another without seeing in it cause of self-grievance, and thus find faults instead of virtues in every character brought within their range of vision, because it can not bear to have another excel. There are the huge, uncomely glasses of greed, that would appropriate to self-gratification all that comes within their line of vision; and the curious parti-colored glasses of policy that convey to the organs of sight the impression of only advantages to be gained, but, strangely enough, exclude that of opportunities (especially parties unable to reciprocate favors). Then we have the pure glasses of contentment, that have the faculty of banishing clouds, and diffusing sunshine; the golden-colored glasses of cheerfulness that create light, and shed a halo of brightness around every object within their range. And there are the wretchedly clouded glasses of ill humor, that reveal naught but clouds and threatened storms, like Tommy's blue panes. But best of all are the beautiful converging glasses of Christian love, that possess the wonderful power of both absorbing and reflecting. They are first themselves warmed by an absorption of the cheering, revivifying rays of the Sun of Righteousness, and then they freely dispense these rays to all about them, causing the widow's heart to sing for joy, the very wilderness and solitary place to be glad for them, and the desert to blossom as the rose. What sort of glasses do we wear?

AUNT VIC.

Rockton, Ill.

We thank you, Aunt Vic, for this plain lesson, which I am sure we all need. I have sometimes thought that a selfish person looked through selfish glasses, for he is generally the most forward to accuse those who are working with pure motives, of being governed by selfishness; and so it is with almost all other sins, while those who are pure in heart, and working hard and honestly, do not seem to notice that the rest of the world is not doing the same thing. You see, they are pure-minded themselves, and wear pure-minded glasses. It seems to me some

of this talk you have given us will apply very well to some of the things we have in our bee-journals now and then. Now let us all take the lesson home to ourselves, without looking to see if it hits our neighbors. It fits me, Aunt Vic, and I resolved to do better before I got through reading your article.

TRUE BRAVERY.

WHO WAS IT THAT WAS COWARDLY?

A COLD sleety night several men were hurrying down the street, on their homeward way, after a day of toil. As the stormy wind swept by and blew the frozen rain in their faces, they buttoned their coats more closely, and pressed onward. But their pace slackened as they approached a brilliantly lighted building from which issued sounds of hilarity and mirth; and, as if from confirmed habit, they paused before the inviting doorway.

"Come, boys, let us take something to warm us up," spake one of the group, and "Good! good!" was echoed by all voices but *one*—a tall, vigorous young man who was about to pass on, when a companion, laying a hand on his shoulder, arrested his progress, saying,—

"What is your hurry, Tom? Join us and we will have a jolly time, if the night is blustering;" and before he could reply or expostulate he was unwillingly borne into the drinking-saloon, where well-filled glasses were speedily supplied the party, who emptied their contents, unobservant that Tom Denton's glass remained untouched on the counter. But as soon as they became aware of the fact, an ominous murmuring ran through the group. Denis Roman's voice broke the pause that followed; he was a man of a strong though mistaken sense of honor; and in his opinion, he who turned his back upon his comrades, and refused to partake of their convivialities, was a traitor, and his act high treason.

"Tom is *afraid* to drink, I see," he said in a mocking tone; "may be his wife keeps him in leading-strings; I did not know before that one of our number was a *coward*."

The hot blood mounted to Tom Denton's face; his hand was tightly clenched, and he bit his lip as if to keep back an angry reply.

"Tom is no coward," broke in another hearty voice. "Who was it that ran in front of the engine last summer, and risked his life to save a little lame boy, playing on the track? Who but Tom? I tell you, Tom is no coward."

"No, no, no!" echoed many voices, and the tide began to turn in Tom's favor.

A smile lit up Tom Denton's manly countenance, and, turning, he was about to leave the saloon in silence, when several spoke:

"Do as you please about the drink, Tom; but make us a speech before you go."

"A speech! a speech!" all cried out. Tom was an uneducated laboring man, but his heart was brave and true, and he was not one to shrink from his duty, or to decline striking a blow for the right when in his power.

"You wish to know *why* I will not drink with you," he said, in a clear loud voice. "I am proud, yes, proud, but not with the false pride that would make me feel that I was better than my fellow-men,

or cause me to withhold the right hand of friendship from my comrades; but the pride that raises me above all that is little, mean, and low. I live in a free country, and am a free man, and I *will not* be a slave to drink. I have a good wife and two little ones; we are poor, but are trying to save money to buy a home, and drink won't help me to do that. I want to merit the respect of those around me; will drink help me there? I will not have my wife pitied, and sneered at as the wife of a drunkard, and my little boys spoken of as drunkard's children. I do not want any man on his death-bed to say to me, 'I am lost; you are the cause of it; you set me the example; you gave me my first drink; I am lost through you.' There is a curse pronounced upon the drunkard. *I am afraid!* in the fear and love of God, I dare not drink."

And as he finished and stood there with folded arms, and the fire of truth in his eyes, though his garments were coarse and his hands brown with toil, he was as noble as a king, and as brave as famous warriors; one of whom the whole community should be proud.

There is a good and tender chord in the heart of every man, if we only know how to touch it; and now the saloon rang with the cry, "He is right! he is right! three cheers for Tom Denton." And he who possessed the courage to brave the sneers and ridicule of his companions, rather than yield his firm convictions of right, or countenance an evil his whole soul loathed and condemned, had probably that night sown some good seed which might spring up and bear fruit in after days. With a firm tread he left the saloon, and walked down the street to the humble happy home awaiting him, while out on the night air rang again and again the tribute to true bravery, "Three cheers for Tom Denton."

MRS. D. TACKER.

Now, little friends, whose shoes would you rather stand in—poor Tom's, as he went off home that night, or in those of the men whom he left behind him?

A GOOD HONEST REPORT FROM A BEE-KEEPER'S DAUGHTER.

WAITING UNTIL AFTER SWARMING, BEFORE PUTTING ON THE SURPLUS RECEPTACLES.

FATHER says he had no report to send in this year; but I think every bee-keeper ought to send in his report every year, whether it is a good or a bad one. So I write to tell you we are not quite ready to go into Blasted Hopes yet. The honey crop was almost an entire failure here. We got only about 1000 lbs. Sold 830 lbs., 12½ cts. per lb. There were only three others, that we know of, in all the country around, that got even a taste of honey, and some got only a few pounds. We started the spring of 1884 with 51 colonies; increased to only 69, as we worked after the plan of Prof. Cook (see June GLEANINGS, page 376, 1884). Others waited till their bees were done swarming, before they put section boxes on; and by the time they were done swarming there was nothing for them to make honey of. All the honey we got was made before the 4th of July. This fall we doubled up some of ours; fed some, and went into winter quarters with 58 colonies. LOUISA C. KENNEDY.

Farmingdale, Ill., Dec. 29, 1884.

Thank you, friend Louisa. I agree with

you, that reports should be sent in, even if not encouraging. You bring out one very important point; and since you mention it, I remember that a great many old-style bee-keepers used to say that if you put on boxes too soon the bees would not swarm, and so they waited until the bees were done swarming, and the result was often just about as you state it.

MINNIE'S TRIALS.

I WONDER if any of the other little girls who read GLEANINGS have as many trials as our Minnie. I hope not; but if you do, perhaps her experience will cheer you up. Last week we went up to school, and one of the girls met Minnie with "It's examination-to-day," and Minnie, sighing from the very soles of her shoes, said, "Is that so?" And all that day she wrote and wrote, working one example after another, eating no dinner, taking a two-minutes' walk by way of exercise, and when I went for her at four o'clock she came out and said she would not be through for an hour yet, and I left her and came home alone. Minnie wrote as long as she could see, then went home with a schoolmate, and they wrote and recited to each other till nine o'clock, and all next day it was write, write, write, till after four. That night she sang all night in her sleep, sang hymns and snatches of comic songs, all night long. Next day was Thanksgiving, and I had put the turkey to roast, and I wanted to leave it to do other work, so I went in the parlor (where Minnie had been working all the morning on an example in algebra) and asked her to sit by the kitchen stove and baste the turkey. She seemed stunned at first. "Why," said she, "I've been working all the morning on this example, giving my whole mind to it, and I can't get it; how could I do any thing with a turkey to mind?" I told her I thought she was giving too much of her mind to it, that perhaps she could get the answer sooner if she gave half of her attention to the turkey. She went with a down-in-the-mouth, dejected look, and in about half an hour she came bounding back. "I've got it, mamma; I've got it! and it was the very smallest thing that ailed it all along; I wish you had set me to basting the turkey long ago." Then she flew to the organ and played "Captain Jinks" and "Yankee Doodle," and ended with "Hail Columbia."

I was glad that her mind was relieved, for I had made up my mind, made it up as the laws of the Medes were made, that if she sang in her sleep another night, she should not go another day to that school. I don't care if it is the best school in the county, and sends out the best teachers; I won't have one of my children made crazy with these everlasting examinations. Three studies to be gone over in one day, and 160 questions in each, and every pupil must answer 75 of them or be put back in a lower class. It is murder most foul, murder of the brain. Physiologists say that 4 hours of steady brain work is as much as one can stand with impunity; but these girls wrote, and thought up what to write, a constant strain on the mind for 8 hours. I'll have no more of it. If Minnie can go along calmly and quietly, and graduate, I am perfectly willing; but any more of this sleep-talking and song-singing I won't have.

MAHALA B. CHADDOCK.

Vermont, Ill.

You are right, Mrs. C.; children should not be tasked, even during examination time, to such an extent that they get worn out, and talk in their sleep, etc. I have just interviewed Blue Eyes in regard to the matter, and she says in our schools they positively forbid their going without dinner during examination time, and that they also forbid such continued application as you mention. I think your teacher and the principal of your school ought to be interviewed. There may be two sides to the question, and it is well to be thoroughly posted before setting down one's foot, after the manner of the Medes and Persians. I should be inclined to think that Minnie was rather an exception, for the average school-girl is sometimes apt to be dilatory, and inclined to procrastinate. Now, may be even our good friend Minnie neglected her studies in the fore part of the time, thus throwing a great amount of work into a few hours' time. Minnie will forgive me for this suggestion, will she not?

SANTA BARBARA AND THE FAIR.

BY AUNT KATIE.

YOU will remember we had got to Goleta, on our trip to Santa Barbara. We stopped at a farmhouse to get some hay for our horses, and got permission to put our beds on the hay in the big barn; the hay had been baled—that is, pressed into large square bundles, of from one to two hundred pounds, and firmly tied with rope. We got our beds made on those nice smooth bundles, and then got our supper. We spent the evening in the house. The next day we went on to Santa Barbara. As we had not been there for three years we found that it had grown considerably. As we were going into the town we met a covered wagon with some "Catholic sisters" in it. They were knitting as they rode along. When one sees them the first thought is, "God bless them for their goodness!" Many and many a one has been helped by those kind women who have given themselves to such work. The ones we met were going out to a farm they have just out of town, where things are raised by them to use in the St. Vincent school for girls that is kept in the town. Oh such lovely roses, and such green grass and strange trees and shrubs! Lovely cottages, yards fenced neatly, and such a wilderness of green meets the eyes, as we passed one pretty place after another, thinking, well, that is the prettiest we have seen yet; but the next one may be would make us say, "No, I guess this is the prettiest," and so on through one street after another, all through the town. One of the loveliest was a house made of the native redwood, oiled instead of painted, making a rich red-brown color. It was two-storied, and had a handsome porch above and below on three sides of the building. The front was almost covered with a white-rose bush, and it was a mass of white roses. They gleamed out pure and white against the dark background.

In the yard was a magnificent rubber-tree, 20 feet high, and fan palms 10 and 12 feet high, with monstrous fans 3 and 4 feet across, and graceful pepper-trees were dotted about, making a pretty home

picture. We camped in a friend's yard, and then started out for the fair. It was held in the theater building and adjoining yard. The very thought of the two long wide tables filled with the delicious fruit that was in that building sets me longing to see them again, with the privilege of tasting as well as seeing. Our little three-year-old orchard was represented by a plate of large yellow bellflowers; but Lompoc, the temperance colony I have told you about, beat even Santa Barbara in the line of apples. There were apples, pears, quinces, grapes, pomegranates, figs, guavas, persimmons, oranges, lemons, citrons, limes, plums, blackberries, strawberries, raspberries, a bunch of dates, and all kinds of nuts in profusion on those tables. Don't you think we could have a grand feast out of that variety?

Then there was honey in big jars, and comb honey in glass cases, extractors, honey-knives, and last, but not least, a swarm of Holy-Land bees. They, too, were in a glass and wire case, and seemed as contented as could be.

I can not tell you of all the wonderful and useful things I saw, but I must tell you of the dear little babies that were put upon the stage to be looked at, so that the judges might see which was the prettiest and brightest. There were 17, all under two years old. I wondered, while looking at them, what each one's life would be. May be some of those boys and girls will be writing letters to GLEANINGS before long, about bees, and how they help their fathers work; and as Mr. Root tells us in the last number, may be one of them will be president some day. Who knows?

Should be a poor judge about babies, for I think them all pretty, some with one kind of prettiness, and some with another; but I said in my heart, "Please God, bless those little ones, and make them good temperance men and women."

We took our noonday lunches at the W. C. T. Union rooms, and found them doing a good work for those who have no homes wherein to sit and read or talk, or have a good social time. One morning we went up to see the "Old Mission." It is a large stone building, and was built by the Catholic fathers 100 years ago. We were not permitted to enter its walls, as only the priests live there; but we were told that we could see the church, so we went through that, and examined the pictures upon the walls. Some were of Christ, and others of the virgin Mary. They were well preserved, and the church looked very nice. The towers above, where the bells were, were being fixed up; the rest of the building was in a good state of preservation. A large fountain, with fish circulating about in the tank, took the children's eyes. It was fed from a large stream of pure spring water which waters the whole town. Those old "padres" had an eye for beauty when they picked out the site for the mission building. It stands on an eminence two miles from the sea, with a background of grand rugged mountains, and takes in the front, the full sweep of the valley wherein rests the town named for one of their loveliest saints; and though she has been dead for many years, yet her beauty seems to have been left to bless the little city, for beautiful it is with a nameless charm. I tried to see wherein the beauty lies, but could not; but there it is, and all felt the charm, and each and all assent, when asked if they think Santa Barbara beautiful. Besides the view of the valley there lies the chan-

nel and the islands beyond, and a noble sweep of ocean one gets from that point; and above all, the glorious blue ether, softened and shaded by the floating clouds. One can hardly return to the earth again after looking over that charming scene; but as we are of the earth earthy, we had to so descend and prepare for our long ride home.

Los Alamos, Cal.

LETTER FROM A BOY BEE-KEEPER.

CAN A BOY OF 14 WORK EVERY DAY ON THE FARM, AND TAKE CARE OF 19 COLONIES BESIDES?

WE have organized a bee-keepers' association in this county, styled the "Progressive Bee-keepers' Association of Western Illinois," of which I am a member. My bees are in pretty good condition at present, but some are quite weak. I was going to school last fall when the bees should have been attended to, and I could not get time to fix them up, so I just took off the honey and enameled cloth, put on the half-story, with nothing in it but air, and, as you say, gave them a good "letting alone," and they are in pretty good condition now.

We have 19 colonies at present, and my folks expect me to take care of them, and work about all the time on the farm besides. I never saw an improved hive until two years ago, and now I am a bee-keeper, expected to keep every thing in order, just because last spring I had a little "bee-fever" (on a mighty small scale). What do you think of it? Do you think it is too much for a boy of 14 years to begin on?

Bees in this part of the country did not do much last year. I never saw so much white clover in my life, but it didn't make much honey. I think it was on account of the cool nights, for it was the coolest summer I ever knew.

I like the bees, but, "my!" how I hate to get stung! I helped Mr. Norton transfer 15 swarms from box hives to Langstroth (which was the bravest thing I ever did), and I thought I should be braver after that; but one day brother Walter went out to put on some sections where I had taken off some honey, and he got stung all over, and his face swelled up. His eyes were shut, and his lips about half an inch thick, and it pretty nearly "discomfusticated" me, and it seems as if I have been more afraid than ever of the little "critters."

Macomb, Ill., Jan. 3, 1885.

J. E. STICKLE.

My young friend, I do think 19 colonies are almost too many for an average boy of 14 years of age, when he has to work on the farm every day besides. Don't you have a good many holidays, however, when you can work with your bees, if you have a mind to? I do not know of many farmers' boys who have to work on the farm every day in the year. I think your brother Walter had better have a smoker that he knows is working nicely before he starts out again. If he can get along without using the smoker at all, well and good; but it is best to have it right at hand. I always want a whip in driving a horse; but if the horse is half way decent, I expect to keep the whip in the socket during the whole trip; but I always want to see the whip in its place before I start off, no matter what horse I have got.

MINNESOTA.

Report from one of our Old Bachelor Brothers.

FROM 29 TO 66, AND 700 LBS. OF HONEY.

I WILL give a report of my last year's honey crop; although it is not very large—nothing like some of the friends in California, Texas, and Florida, who reported such large yields of honey that it almost seems as if they must have their bees taught to take a pail and dipper when they go to gather honey. I had 29 colonies, spring count, in good condition; by feeding until the dandelions came in I got them very strong. They began to swarm May 27th; but for some reason or other the white clover yielded no more honey then kept them rearing brood. About July 15th, basswood bloomed very abundantly, and then my bees took the swarming fever, and got cross; no one hardly dared go among them; and when a swarm clustered, shaking them into the swarming-box was like knocking against a yellow-jacket's nest (if you ever did that when you were mowing with a scythe, where you could not run a machine). Even tobacco smoke would not subdue them, when taking honey out of the hive. Can you give any reason for their being so cross?

I increased to 66; lost 5 by robbing, when I was making syrup, and not watching them; united 6 weak ones, so I have 55 strong swarms—34 in the cellar, and 21 in chaff hives out doors.

We are having a very severe winter. Jan 2d the mercury went down to 40 degrees below zero; and, as the Irishman said, if the thermometer had been longer, the weather would have been colder; so I don't know how they will winter. They are in chaff tenement hives, of my own make. But I am not ready for Blasted Hopes, as I got about 700 lbs. of comb honey, and raised over 900 bushels of wheat. I did not get a single pound of honey after the basswood ceased blooming; although the goldenrod was quite plentiful, there was no honey in it. Next year I will devote more time to my bees.

I wish you would send me one of those price lists that you spoke of in your last number, and said you had several girls that did not have much to do, and would jump at the chance of sending one; but if you should happen to make a mistake, and send one of the girls, instead of the price list, to any of us bachelor bee-keepers, there would be no fault found.

Did you ever try scattering a little dry dust or ashes over the snow among the bee-hives? It will cause it to melt very quickly; and when the bees fly out, if it gets warm quick, they will not get snow-blind, and tumble in the snow and die, but can alight on the honey-combed snow and rest, and then fly away.

JAMES P. SMITH.

Franconia, Minn., Jan. 5, 1885.

Friend S., the girls here in the office are not a bit better or a bit smarter than those in your own neighborhood; and I think you ought to be ashamed of yourself to think you have not found it out yourself a long while ago. We will send you the price list most cheerfully; but when you want a nice girl for a housekeeper, you must go and get acquainted with her according to the old orthodox manner. There is not any other way in the world that you can get a real good honest sensible girl.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of DAVID COOK'S excellent three-cent Sunday-school books.

Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows, viz.: Sheep Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room. We have now in stock Our Homes, Part I., and Our Homes, Part II.

"A chief's among ye takin' notes:
An' faith, he'll prent it."

WELL, little friends, the carp-pond is frozen over, and almost as smooth as glass; in fact, it is so smooth that I can not get around on it at all. One foot goes forward when I do not want it to, and may be the other goes backward, and then they both go forward or both go backward, or perhaps sideways, and I get to feeling so uncomfortable that I think I would rather be on the ground. But you just ought to see the children fly around on the smooth and glassy surface of the pond. Even Huber fairly crowed and screamed with delight when he caught sight of the merry party of brothers and sisters, with cousin Mabel and uncle Hen as they flew around over the pond. In fact, the pond itself was a great wonderment. A few days ago he had seen the glassy water as it rippled in the breeze; but now it was hard and solid, and so clear that he could look right down and see the weeds and grass at the bottom. We drew him down on his little sled, you know; but we were all so excited, that, just as he got near the edge of the pond, the sled tipped over, and his poor little rosy face went right down on to the hard frozen ground. Mamma had pinned his mittens on, and then wrapped his arms around so he could not help himself a bit; and when I saw him going it hurt me as much, or more, than it hurt him. It was just when he first caught sight of the merry crowd, and was crowing to think he would soon be among them. I gathered him up, and kissed the tears out of his poor little eyes, and kissed the mud off from his poor little bruised pug nose. He tried manfully to keep back the tears, but they would come for a while. I asked him if we should take him home to mamma; but he whined out, amid his sobs, "E-o-you-you-." He means by this, that he does not want to go home. He got this last summer when I took him to see the strawberries, and down to see the lots. Whenever I turned around to go home he would begin a long-drawn-out sort of whimper. It is pretty hard to spell it; but

if you say "ow," and draw out the last letter long, you will get pretty near it. We laughed at him so that he got in the habit of using "ow" as a protest. Whenever he seemed tired of his play, and I asked him if he wanted to go home, or wanted to go in his "hy-by," that is, to get into his crib to go to sleep, if he wanted to play longer he would say "ow," and when he wanted to be more emphatic he would draw out the word still longer. So, even amid his pains and sobs I understood he wanted to play on the pond, and did not want to go home. So we put him on his sled and pushed him from one end of the pond to the other. Of course, everybody understood that when Huber and his sled came along they were to clear the track; and brother Ernest on his skates would back out of Huber's way with such grotesque grimaces that the baby's tears of pain had to give way to laughter pretty soon. After he had been there about half an hour I noticed a great big bunch coming up on his forehead, so large that it alarmed me, and in spite of his "ows" very long drawn out, I decided to take him home to mamma.

Well, the carp-pond has paid for itself already, even if it is true that it contains only a dozen little carp; and it seems to me some such pond should be furnished for every family of children, for a place to slide and play in winter, if for nothing else. It is a cheap amusement, comparatively; and with good companions it is innocent; and where is the doctor that would not tell us it is healthful for children to fly around as if they had wings, instead of feet, in the frosty open air? Blue Eyes fell right down flat; and as she is a pretty big girl now, it almost made the ice crack. Mamma had to come down to see the pond too, and I told her that she could not stand up on it "no way." She replied with some of the old animation I used to see in her girlhood, "Can't I, though?" And she ran right down on the pond as recklessly as a lot of young ducks would run away from the mother hen, and go into the water; and, would you believe it? she didn't slip down once, but just skimmed over the ice like a bird, here and there and everywhere; and it tickled Huber almost out of his little senses to see his mamma suddenly become a child like the other children—at least while she was on the glassy surface of that little carp-pond.

FOREST-LEAVES FOR CELLAR WINTERING.

My pa put 53 swarms in the cellar. He put leaves in the top of some of the hives.

M. A. AXTELL, age 8.

Strawberry, Iowa, Dec. 12, 1884.

MINNIE'S REPORT.

My pa has 17 stands of bees. I have a sister, her name is Alice. My pa lost only one hive. He got 300 lbs. of honey in one month from one hive.

Amity, N. Y., Dec. 10, 1884. MAMIE UTTER.

LEOMA'S LETTER.

I live with my uncle, Mr. Prior; he keeps bees; he has 20 stands. Had 4 stands in the spring; he increased to 20. He takes GLEANINGS. I like to read the little folks' letters, and I like bees too. I don't go to school in winter. I have a bird.

Hope, Ill., Dec. 23, 1884. LEOMA DAVIS, age 9.

ABOUT OUR CAT.

My brother keeps bees; he has the A B C. One year ago last summer our cat caught 3 weasels, and this summer he caught 4.

NETTIE H. CRANSTON, age 10.

Woodstock, Ohio, Nov. 21, 1884.

LUTIE'S LETTER.

MR. ROOT I HAVE ONE STAND OF BEES I HELPED PA HIVE BEES LAST SUMMER. I HAVE A CAT AND A DOG MY DOGS NAME IS ROVER. I GO TO SABBATH SCHOOL.

LUTIE YOCUM, AGE 5

RIVERTON, ILLINOIS, DEC. 31, 1884.

MOVING BEES ON A MUD-BOAT.

Pa's bees are getting along well. They are all right. He has 21 stands of bees. We moved them about a quarter of a mile on the mud-boat, and upset two of them in the snow, and had quite a time. We got them in the hive again all right. Pa put 14 stands in the cellar, and 7 outside.

Mexico, Ind., Dec. 8, 1884. SHERIDAN E. HOWER.

CHARLIE'S REPORT.

Pa had 30 hives of bees last fall. It was so cold that pa had to unite 8 hives, and feed all of them for winter. It was so dry last summer that we did not get much honey. Pa says he will have to raise 19 queens, early next spring, to take the place of old ones. His bees did not swarm last summer.

CHARLIE O. PERKINS, age 9.

El Dorado, Kan., Dec. 30, 1884.

MINNIE'S IDEAS IN REGARD TO SWARMS ALIGHTING IN THE SAME PLACE TWICE.

Papa has 10 hives of bees now; they swarmed 6 times, and they never alighted in the same tree twice. If they do that next year I think alighting on same limb twice is all bosh. I have a baby brother; he is like little Huber; he likes to play in the coal pail.

MINNIE R. ANDERSON, age 7.

Greenfield, Iowa, Dec. 30, 1884.

FIVE HIVES OF BEES FOR \$50.00.

Papa has sold five hives of bees for \$10 apiece, but we've got some more yet. Papa is going to buy some more. His bees have been housed up ever since Christmas, until day before yesterday; the weather turned warm, and they are having a fine time, and doing well.

NANNIE AUSTIN, age 6.

Austin Springs, Tenn., Dec. 31, 1884.

A LETTER FROM A THREE-YEAR-OLD "CHICK."

Papa has got lots of bees, and I's afraid of dem. I likes honey and bisits. I don't go to day school, but I go to Sunday-school; papa takes GLEANINGS, and I like to hear him read about bees. As I tan't write meself, I get Uncle George to write for me.

JENNIE A. AUSTIN, age 3.

Pretty good, Jennie; but I guessed somebody wrote your letter for you. I shouldn't wonder, however, if you told it to them, because some of your words sound very much like a three-year-old little girl.

STELLA'S AND ALTIE'S BEES.

We keep bees. Those bees we got from you are doing well. I have 5 bee-hives—one Italian and the rest are black. The moths bother our bees in the spring. We put salt around the stand. I help with the bees. I like to work with bees. STELLA COX.

We transferred 3 stands of bees last spring. We use comb foundation. I like to put in foundation. We have 90 bee-stands. This is my first letter.

Springerton, Ill., Dec. 28, 1884. ALTIE COX.

HARRY'S BEE-FEEDER.

Here is the description of a cheap and easily made bee-feeder: Take an oyster-can, cut out one side, and pound the edges down smooth, then take about six pieces of wood, just about long enough to go in the can without touching, and far enough apart for the bees to get their heads between them; then take two pieces just long enough to go in crosswise, and tack them on at each end, to hold the other pieces together. This frame will float on the syrup, so the bees will be handy to the honey, and the weak ones will not get drowned.

HARRY SCUDDER.

Greenwood, Ind., Nov. 17, 1884.

WHY THE BEES WOULDN'T STAY IN THE HIVE.

My ma has two colonies of black bees, and we got about 15 lbs. of honey in the comb. Mr. Dinnit has two colonies of Italian bees that he brought from Indiana; he got his queen from you. Please tell me what made our bees come out of the hive. We settled them three times before they would stay in the hive.

MINNIE BINGHAM, age 13.

Lamar, Mo., Dec. 30, 1884.

Well, Minnie, it is a pretty big question to answer, as to why your bees would not stay in the hive, even after having been put back two or three times. The A B C book is full of the matter, and there have been many long articles written in regard to it in the back volumes.

A LETTER FROM CANADA.

I have a swarm of Holy-Land bees. They are in the cellar. It was ten degrees below zero last night, and it is very cold to-night. We can hardly keep the cellar warm enough. My bees are in a Langstroth hive, but pa extracted from them last summer. I don't know how much honey they made, for pa extracted it with his. He is going to sow some aliske clover next spring. It makes the best and most honey, the best hay, and the highest-priced seed.

SELA W. MICHENER, age 8.

Low Banks, Can., Dec. 30, 1884.

JACOB'S LETTER "SHEARING" QUEENS' WINGS.

I like bees. I am staying with my uncle; we have 7 stands of bees now. We had 13 bees this summer. I think bees do accordingly more than men. We took corn fodder and straw to pack our bees for winter. Last year we had 13 stands, and got 28 gallons, and seven boxes of pure comb honey. I think we took 25 gallons out this year. My uncle gets GLEANINGS. I helped to catch queens, to shear one of their wings off so they wouldn't fly. We still separate our bees. We do not like to get them when they hang high up in a tree. I have no bees. I have seen black bees and the kind Italians. Italian bees are very nice looking.

JACOB A. MILLER.

LaGrange, Ind.

GEORGE'S BEE-KEEPING.

I bought one swarm of black bees in a box hive, and had a swarm of hybrids in a box hive given to me. In the summer of 1883 a swarm of bees clustered on my father's house. Papa hived them; they did not have enough to winter on, so I took them up. Then I thought I'd like to keep bees in 1884, and see if I liked the business, and now I like it well. From the black swarm I got one swarm this fall, and killed the young swarm and the mother colony, and got about 40 lbs. of honey. The hybrids gave me 2 swarms. I am uniting the 2 young swarms. I have one swarm in a Langstroth hive. I

think I shall get an extractor when I get enough money. I have sent for some sections.

GEORGE J. WILSON, age 13.

Ridgefield, Ct., Nov. 25, 1884.

Why, George, what in the world did you kill the young swarm and the mother colony for? Are you not a little bit behind the times? We do not kill queens nowadays to get the honey. It is like killing the goose that lays the golden egg.

SALT AND HONEY FOR A COLD; ALSO SOMETHING ABOUT SARAH'S LITTLE BABY-SISTER.

I am going to tell you about my little baby-sister. She is 16 months old the 10th of this month, and I think she is just as big a mischief as Huber. She is running around all the time, except when she is sick or sleeping. She makes every one of us do just as she likes. She was sick with a cold, and ma mixed some salt and honey, and gave it to her, and she soon got relief. It is very good when any one is choked up with a cold.

The bees out here did not get as much honey this year as they did last, for the season was short. I help pa with the bees in the summer. The imported queen he got from you is the best he ever had, and he says he can handle them without veil or smoker. Pa has 58 swarms this fall.

SARAH A. CHRISTIAN, age 13.

Lorraine, Ont., Canada.

BUCKWHEAT AND CARP-PONDS.

Uncle Will sowed 2½ acres of buckwheat, and had 60 bushels. I don't know much about raising carp, but I know one of our neighbors had a great deal of trouble making the dam so that the crabs would not make holes in it. If this is worth a book please send me Pilgrim's Progress.

MINERVA DUNCAN, age 10.

Black Lick, Pa., Dec. 1, 1884.

Of course, your letter is worth a book, Minerva. It was only night before last that we found a hole through the bank of our carp-pond, large enough for a kitten to crawl through, and the water was gurgling out just as fast as could be. Will went and got some good yellow clay and puddled it, and pounded it into the hole, and that stopped it. Now the question is, "What made that hole?" I should not wonder if it were those pesky crabs you tell about, for the hole was made just on a level with the water's edge in the pond, and went down through the bank into the creek that runs by the side of the pond. If there are any more such troubles we are going to draw some tin scrap down to the pond and make the horses tramp it in well along by the edge of the water.

GETTING BEES DOWN OUT OF THE TREE: MARY'S PAPA'S BEE-ARMOR OF OIL-CLOTH.

My pa has 29 swarms of bees. Our bees did not make very much honey this season. One day last July pa went to town, and the bees swarmed, and I went after my brother to come and hive them. Five swarms came out at once, and two went away, and the other three alighted in one tree. My brother climbed the tree and sawed the limbs off that had the bees on, and then took a rope and tied it around the limbs, and then let them down beside the hives. Pa has an oil-cloth shirt, to handle bees. He puts that on, and then an oil-cloth hood with

wire screen in front, so he can see. He puts his sleeves in his gloves, and ties strings around them, then the bees can't sting him. Our bees have hot feet.

MARY WING, age 12.

Lamont, Iowa, Nov. 26, 1884.

Your papa's bee-armor is quite a novel arrangement, Mary, and no doubt it would be very convenient for one who is afraid of stings; but I think I would rather not have it.

ORRIE'S LITTLE LETTER.

I live in Ghent. My aunt Viola keeps bees. She has about 50 swarms. They did pretty well. She has some in the round house, and the rest on summer stands, packed. We live by a stream called Yellow Creek. I have got a little sister Mary, and a little brother Tommy.

ORRIE PIERSON, age 8.

Ghent, Ohio, Dec. 7, 1884.

Thank you, Orrie. Your grandpa used to be one of my particular friends before he died. I am very glad to know one of his daughters has taken up bees, for I suppose your aunt is one of his daughters. I used to visit your place occasionally, down by that beautiful little stream, and I think you have a very pretty place to live.

ELLA'S LETTER JUST AS SHE WROTE IT.

Weil Unkle Am's i rote you se i letter And received my Book. I can Not Readsin it to Me. When pa was looKing throug thø Bees My Lit TIE BrotherstooD By the wilees And sald he Was Go to beaB ma N. PA Has 26 CoLinies of gees i Like to be LPPa E*traot and eat The cAPiNs: I do not Go to sØho>L moW i wolId like to go to SchoolBut It is to Fer for Me i e arn sØme at Homø. Unkle Amo's if thIs letter is WorthaBook Ple asend me SilVerKee.

ELLA KIRK.

Columbus, Kan., Dec. 6, 1884.

But you did not tell us how old you are, Ella. From the looks of the letters you make, and from the fact that you could not read your book, we think you must be pretty young.

CLARENCE'S EXPERIENCE IN HUNTING QUEENS ON HIS OWN HOOK.

I will tell you my experiment in bee culture. Last summer my mother gave me a swarm of bees. I used to help my father to hunt the queens. One day he was away, and I thought I would hunt the queen in my hive, but I could not find her. Then I opened one of pa's hives. The bees got after me in great numbers, and stung me. I "hollered," and ma came running to help me. They got after her, and she ran in the smoke-house and shut the door, and I ran in the hitchen, and they after me, stinging. Then I ran into the stable and got behind the door, and the bees went home. I have not hunted queens alone since that time.

Zearing, Iowa.

CLARENCE HASLET, age 8.

HOW ARTHUR'S FATHER MOVED THE BEES ON A LOAD OF STRAW.

We moved our bees the middle of October, about two miles. I have 2 lambs, named Smut and Dick, and I have some ducks and chickens. I did not have room for any before I lived on a farm.

I will tell you how we moved our bees. Pa took a hay-rack, and put on a good load of straw, and set the hives on, and stuffed straw between the hives.

We moved 55 swarms in two loads, in nice condition. They had a nice fly the next day, and not one bee went back to its old home. They sat in an orchard, and had their last fly the 23d of November, and pa put them in the cellar the 24th, the latest they ever flew. Our bee-cellar is under our house, and is a nice large one.

ARTHUR W. HULETT, age 12.

South Dayton, N. Y., Nov. 19, 1884.

ADA'S STORY ABOUT THE SWARM OF BEES THAT ALIGHTED ON HER MAMMA'S BACK.

My papa keeps bees. He has 139 stands. He has them all in the cellar, except 5, which are in chaff hives. I think bees are very nice little pets, if you don't handle them too roughly. Last summer mamma was trying to hive a swarm; it arose and came down, and alighted on her back. She got down from the ladder and stood over the hive while I brushed them off into the hive. I have read Ada Kreeker's letters; and as my name is Ada too, I should like to correspond with her. I should like to know her full address. ADA C. STEINEBACH, age 13.

Cedar Creek, Wis., Dec. 22, 1884.

Thank you, Ada; but you did not tell us whether your mamma got stung or not. The address we use in writing to Ada Kreeker is Tokio, Japan.

THE SPECKLED BANTAM HEN THAT HAD TWO CHICKS FOUR TIMES AS LARGE AS HERSELF.

We have four swarms of bees. I have one sister. Her name is Myrtie. We have some bantam chickens. Myrtie's are speckled, black and white. Mine are black. We put some Brahma eggs under my hen, and she hatched two, and kept them till half grown. It was comical to see her clucking around, followed closely by two chicks four times larger than herself. But a weasel got into the coop one night, and killed both the chicks, and it was pitiful to see the little mother in the morning looking sorrowfully down upon her dead chicks.

Gilford, Mich.

LILLIE GRAY.

That is a very good little story, Lillie. Poor little Bantam mother! No doubt she loved her great awkward chickens as well as if they had been diminutive like herself. Your little letter just reminds me of the Bantams I used to have when I was a boy; yes, and Brahmas too. I declare, I should enjoy being out among them this sunshiny January morning, if I had the time, and I do not know but I should love them just as much as I did when I was only a boy a dozen years old.

THE BEES THAT WENT TO THE WOODS, AND WENT INTO A KNOT-HOLE, ETC.

I will give our report for the season. We commenced last fall with one colony; it wintered all right, and so we bought another one in a box hive, but it died of starvation, because we could not look in the hive, and it was too early to transfer. He bought another one that swarmed once, but my brother had the queen's wings clipped, and they went back into the hive, but the queen was lost, and he bought another one, a dollar queen. He had it two days, when it swarmed and went to the woods. It went over half a dozen trees, and clustered on the knot of a tree. We got a ladder, and brushed some off, but they went right up again, and pretty soon we found they went into the tree, so we let them stay there. We divided the rest twice, but

had to feed them. We took 50 lbs. from the other colony. It seems hard to believe that some take from 200 to 400 lbs. per colony.

We take GLEANINGS, and we have an A B C book, and I read it so much that my folks call it my "testament." My brother bought 500 sections, 100 L. frames, 7 lbs. fdn. and a smoker. A smoker is nice to start fire with. We have all our bees in splendid condition for winter, in chaff hives, which my brother made. He has lumber enough for 30 or 40 hives. Here is an example: My age, plus $\frac{1}{2}$ of my age, plus $\frac{1}{4}$ of my age, plus 3, equals my age. What is my age?

HARVEY BAER.

Marshallville, O., Dec. 11, 1884.

Very good, Harvey. I wonder how many of the little folks can tell your age from your statement. I am inclined to think that they will need a little bit of experience in algebra to work it out; don't you think so?

ONLY 75 LBS. OF HONEY FROM 43 COLONIES OF BEES, AND HAD TO FEED BESIDES.

Pa has 43 colonies of bees. Our bees did not make much honey this year; we got only 75 lbs. of honey this year. We have put all of our bees in the cellar this winter. Some of them have not enough honey. We had to give them some of the surplus that the other bees made. One of them we are going to feed with rock candy. Our cellar is a dry warm one. Our bees wintered in it very well last winter. Pa gives me half of the price of the queens that are introduced to the neighboring bee-keepers.

TWO QUEENS HATCHED UNDER A SITTING HEN.

I hatched five nice Italians under an old sitting hen. I can run the wax and honey extractors, and foundation-mill too. Pa says this is going to be a hard winter for bees to all live through.

JOHN ROBERTS.

Schoolhill, Wis., Dec. 16, 1884.

Very good, John. It seems to me the children tell us the bad reports, even if the older ones do not. What did you put your queen-cells into when you put them under the sitting hen? Some years ago I suggested taking small round tobacco-boxes, and painting them white, so they would look a good deal like eggs. I think the old biddy would keep up the proper temperature at a comparatively small expense.

MORE ABOUT THE GERMAN CARP.

As you wished for information about carp, I have a little to offer, having seen the golden that are imported from southern China. Almost every one knows how interesting they are; but I know the German carp abound in Polish Prussia. They are there a great article of commerce, and are sent from there in "well" boats. By some they are considered the queen of rivers. They were known in England as early as 1496, and have become naturalized to their water. It is considered a good, stately, and subtle fish. They thrive best when the current is not strong, and when the ground is soft and marly. They eat scarcely any thing in the winter months, but bury themselves in the mud. They lose their shyness by visiting their ponds and feeding them on bread and boiled potatoes.

KEEPING FISH ALIVE OUT OF THE WATER FOR TWO OR THREE WEEKS.

In Holland they keep them alive two or three weeks by hanging them in nets filled with wet moss, and feeding them on bread soaked in milk. They

are prodigious breeders, and so cunning that they are styled the "river fox." The tail of the carp is bifid, and they belong to the order of the *Malacopterygia al dominalis*; "these fishes have the skeleton osseous, jaw complete, bronchia plicated, all of the rays of the fins soft, except sometimes the first ray of the dorsal, or pectoral fins; ventral fins behind the abdomen."

By the way, Mr. Root, were you thinking of carp when you put your bees, 250 in number, up for winter? You are not quite as small a bee-keeper as the one who had only 15 bees.

Nashotah, Wis.

NELLIE M. OLSEN.

Very good, Nellie. But, is it really a fact about fish living three weeks out of water? If so, I shall have to say again: "What a world of wonders this is!" We are in the habit of using the expression, "Like a fish out of water;" but now it happens that they live and eat and drink (that is what you mean is it not, Nellie?) and do not die, even when two or three weeks out of water.—I guess I shall have to own up about the 250 bees. Pretty good joke on Uncle Amos, is it not, when he smiled a little at the girl for saying that they had only 15 bees, and then afterward tells about 250 himself.

GEORGE'S FATHER.

My pa has 7 stands of bees. Three are in box hives, and four in frame. He transferred two frames last fall. He took 200 lbs. of honey, and fed them on sugar syrup. They are doing nicely now. Pa takes GLEANINGS, and we like it very much. He has the A B C book, and ma says he reads it more than he does his Bible, and that he thinks more of his bees than he does of her.

GEORGE CASE.

Cornwall, N. Y., Dec. 21, 1884.

Well, George, I do not know but I shall have to take your pa's part a little. May be just now it is necessary that he study GLEANINGS and his A B C book a good deal. I suppose that by this time he has the greater part of the Bible in his heart, so that it shines out in his daily life, even if he does not read it as much as the bee-books, and I should say it was something the same way with your mother. The subject of bees is new, and he gives it more attention now, perhaps, than these other things. Do you remember that story in the Bible, about the prodigal son? The elder brother complained because the father paid so much attention to that spendthrift boy when he got back; but the father had not for a moment forgotten the faithful and diligent son, even though appearances might have looked a little that way to an outsider.

NANNIE'S STORY ABOUT THE CARP-POND.

Uncle Amos:—May be I ought not call you that, because you do not know me; but I know you; that is, through GLEANINGS. Other boys and girls call you that, so I thought I would. Papa keeps bees, and has taken GLEANINGS ever since I can remember, and I like to read the juvenile letters.

I will tell you about our carp-pond. The man we bought the farm of, says he has known the pond for 65 years, and it has never been dry in all that time. He says the old hunters claim that they found beavers in it. We have enlarged it so that it covers about a third of an acre. The original pond is just the shape of a bowl. Papa applied to the U.

S. Fish Commissioner for the German carp; and when the fish came, the pond had about one foot of water in it. There were 25 fish from 3 to 7 inches long. For the first few days they seemed to be doing well. The pond is surrounded by forest trees, and one cold windy day a great many leaves blew into the pond, and then it froze over. After the ice thawed out, papa went down to the pond and he saw a dead fish floating on the surface of the water. He got a rake and raked all the leaves out along the shore; and before he got through he found 16 dead fish. He did not know the cause, unless it is that the body of water was so small, and the leaves seemed to make the water unfit for the fish. The pond is filling up rapidly, and papa is going to try again.

NANNIE STEHLE, age 13.

Marietta, Wash. Co., O., Dec. 21, 1884.

Thank you, Nannie. Was not the trouble because your pond was too shallow? The books say there ought to be places in the pond at least three feet deep for the fish to get into when the water is frozen. May be the leaves would make the water unfit for fish, but I hardly think so, for carp are very hardy.

SOPHIA AND HER MOTHER AND THE BEES.

My papa has 90 hives of bees, all in good condition; they are all Italians. This last summer was a poor season for bees. We got very little surplus honey. It was too cold and dry in our neighborhood. My mother and we three children tend to the bees all summer. My papa has been supervisor for the last two years, so he doesn't get time to tend to the bees. Mother can handle the bees better than father can. They don't sting her half as much. She can go in among them, and work with them bareheaded, and don't get stung; but we put our bee-caps on. They don't like us so well. We get stung very often, but we have got so used to it that we don't mind it. We have lots of work with bees in summer. They always paid us well for our trouble, except this last summer. Year before last we got about 2000 lbs. of honey, all put up in one and two pound sections. I tell you, we felt proud, as many a dollar we made out of it. We get 20 cts. a pound, or we generally give 6 lbs. for a dollar. But father says we must not get discouraged. May be next summer they will do well again, and pay us double.

Father wants to get a Holy-Land queen this next summer. I wish you would tell us if they are better than the Italians, and if you keep them for sale. My father is much obliged for the bee-books you sent him. He is a poor scholar himself. He generally gets me to read the journals, or else my mother does; but she hardly ever has time to read. I read to him some evenings; but I have my school lessons to study. Father means to send me to high school next winter.

SOPHIA P. SCHNERR, age 12.

Shrewsbury, Pa., Jan. 1, 1885.

That is a real good honest letter, my little friend, and I am very glad to know that your mother can handle the bees so well. Your report may be an encouragement for other mothers; who knows? We have the Holy-Land queens for sale, but we do not find them superior as honey-gatherers; but they have many very valuable traits, especially where one wants a good many queen-cells built, or where we want to increase colonies rapidly.

OUR HOMES.

But one thing is needful; and Mary hath chosen that good part, which shall not be taken away from her.—LUKE 10: 42.

I WANT to call your attention this morning, friends, to a simple little story. It is all told in five short verses—the last verses of the tenth chapter of Luke. There is something to me wonderfully interesting in these little sketches, because they tell me of the habits of our Savior, and they give us an insight into that wonderful character of God and man in one. It seems to me that Jesus knew this family before this little story is taken up. It was just after he had given instruction to his disciples in regard to going forth. The beginning of that chapter has that text in it about the harvest and the laborers. The seventy had gone out and returned, and he has been talking to them. It was at the same time that the lawyer stood up and asked what he should do to inherit eternal life, and then he tells them the story of the good Samaritan. Finally they come into this village. This village is Bethany, near Jerusalem. You will remember that our Lord was wont to stop there, and we have reason to feel that he had an especial friendship and love for these two sisters and their brother. Martha probably had charge of the housework. Perhaps she was older than her sister Mary. Perhaps Jesus had sent word beforehand that he would stay with them; and what woman is there who would not have felt anxious to have every thing about the household decent and in order, when that humble house is to be honored by the bodily presence of the Savior of the world?

Martha had a sister called Mary, and we are told in one brief line that Mary was much in the habit of sitting at Jesus' feet, where she sat to hear his words. Teachers in olden times taught while sitting. We read that the demoniac, after he was healed, was found sitting at Jesus' feet, clothed and in his right mind. We also learn that Paul was taught at the feet of Gamaliel. So we have something of an idea of the mode of teaching in ancient times. We can imagine the Savior with a group of followers as he had nearly if not all the time about him. Pupils we might call them. Mary, we have reason to suppose, was very earnest and very anxious. Perhaps he sat down in the doorway, or near their residence. While Mary was deeply anxious that no word that fell from his lips should escape her, she was also modest and retiring; and that she might not be in the way of others, who were equally anxious, she probably shrank down near the ground, while at the same time she crowded near to him. In that mild climate it was quite customary for hearers or pupils to sit on the ground. I am inclined to think that Mary was diligent, and ordinarily assisted her sister Martha, and did her full share of the housework. But some one told her the Master was coming, and in her zeal and love for him she forgot the housework and preparations for supper, and with the rest of the people of the village gathered

about him. Both sisters were probably human, like ourselves; but while Mary was intent on the Master's words, Martha was anxious and worried about the supper. You know how it is, dear reader, to be just on the jump to get ready in time for something or somebody, and then find your right-hand helper missing. Can we blame poor Martha for getting impatient and fretful? She had got into that frame of mind where she could take in or see nothing but the necessary housework before her, and she straightway decided in her own mind that she was doing exactly right, and Mary was sadly out of the path of duty. Luke explains it all in a few brief words in that fortieth verse: "But Martha was cumbered about much serving." Are there any words in our language that will tell it any better? So intent was she with this thought in her mind that she comes to the Savior and complains, saying, "Lord, dost thou not care that my sister hath left me to serve alone? Bid her, therefore, that she help me."

Martha was no doubt an excellent housekeeper. Whatsoever was to be done was done in her house according to the Bible maxim, "Decently and in order;" and decently and in order the work should be done as long as she was spared to manage. It was a burning shame that Mary should put off that way, just at a time she was needed above all times, with such a shocking disregard and indifference to the fact that the Savior was at their house. I presume not a doubt entered her mind but that Jesus would at once rebuke Mary for her shortcomings, and bid her attend to the important duties devolving upon her.

Let us pause a moment and see if we can remember when Jesus took the responsibility upon himself of settling little differences between brothers and sisters, or neighbors, if you choose, by deciding in favor of either one or the other party. A man once came to him, wishing him to make his brother divide the property fairly. I have often thought of that answer—"Man, who made me a divider over thee?" He whom the winds and the waters obeyed, declined assuming the responsibility of saying who was right or who was wrong in these little differences. He gave general rules, it is true, for the adjustment of all quarrels and disagreements; but he did not deem it within his province to say to anybody, "You are right and your neighbor is wrong." In this case it is true he commended Mary, and at the same time he kindly and lovingly gave Martha a few words of caution. Poor Martha, like many a good housewife, had been getting her housework and her daily cares and duties a little before the obligations due to her God. We are told, away back in the Old Testament, "Thou shalt have no other gods before me," and I presume our friend Martha never dreamed that her housework and spotless china (I was going to add silver spoons and such things as we have when distinguished guests are expected to tea, but very likely they had none of those things) were getting to be of more importance to her than her duties in regard to eternal life. But any way, she had mag-

nified the importance of these things, and had forgotten the other. I presume the Savior had told them before this to "seek ye first the kingdom of God and his righteousness, and all these things shall be added unto you." But if he did, she had forgotten it, and had forgotten, too, how nearly her sister Mary, of whom she had been complaining, was heeding that sacred injunction. He repeats her name twice, as it were, in loving rebuke: "Martha, Martha, thou art careful and troubled about many things." He goes on with the wonderful words of our text: "But one thing is needful." Perhaps he paused a little here until Martha began wondering what was that one thing we need above all others in this world. As if in answer to that query, he adds, "Mary hath chosen that good part that shall not be taken away from her."

You will notice, friends, that a part of Christ's words seem applicable to the people and subjects right before him. But every now and then we have expressions that have been handed down to us as texts that apply to the present, past, and future, and, in fact, to all time to come. One of these texts was uttered right here, and I have chosen it for a text for my remarks: "But one thing is needful." That applies to you and me as well as to Mary and Martha, and all that assembly. What is the one thing needful in this world? I do not suppose the Savior meant that other things are of no importance at all, for of course no reasonable being would understand we are to give up the housework and the business of our daily life, and spend all our time in reading the Bible, or going to meeting. I have sometimes thought that some people read the Bible too much. Of course, this is not very often the case, but there are sometimes duties that are, for the time being, more important than Bible study, and therefore, if one wants to be a good Christian, it is by taking up his duties in life, rather than reading the Bible when he ought to be doing something else. Perhaps I can make my meaning plainer if I put it something this way: There are revival meetings in our town at present, or, at least, souls are being saved in a quiet, orderly sort of way. I think Christians ought to make quite an effort to be present at these meetings. A great many say that they can not get away from home, and may be this is true. But suppose some talented lecturer should come along, and everybody were going out to hear him; under the influence of the excitement about him, perhaps you might make some sort of arrangement and go any way, and you would say the case was unusual, and of great moment. Well, our regular Christian duties are of great moment, and they should be placed first and foremost in importance. Sometimes, under the pressure of circumstances, we let supper go entirely, or pick up something that answers for the special occasion, without stopping to go through the regular routine; and I would suggest that the Master would have been better pleased had Martha listened to his teachings as Mary did; and when the time for supper came, made some hasty preparation for the occasion, taking it for granted

that it was of much greater moment to listen to the Savior's teachings than to have an elaborate meal prepared. Now, my friends, have we chosen the "good part," as Mary did, or are we "cumbered about much serving," as was Martha? Almost ever since I found that little story in the Bible, those words, "cumbered about much serving," have rung in my ears. When things go wrong, and I am wanted at several places at once, I get fidgetty, and may be a little cross and fretful, and I do not look happy, as Mary doubtless did, while she sat at the Savior's feet. In fact, right here, while I was dictating this Home Paper for your benefit, but a little time ago, the head shipping-clerk came to me with a couple of hammers in his hand. Said he, "Mr. Root, do you call those steel hammers?"

"By no means; who said they were steel?"

"Why, they have been sending them out for steel hammers, down in the counter store, for some time past."

I took both hammers, and started off with some ejaculation about such kind of work as that. On the way through the office, several clerks stopped me with some inquiries about other things. I wanted to get back to write the Home Papers, because, when the thread of my talk gets snapped off too long I some way lose the spirit, as it were. A good many things had to be righted, and I seemed to be needed in a good many places. I made up my mind that the rest of the Home Papers would have to be left until after dinner, and then we should be in the midst of the daily roar of business. All at once it occurred to me that I was just in the fix poor Martha was when she started to fetch Mary back to her work. "Cumbered with much serving" expresses it exactly. That is just what I was, right in the very midst of sitting down to teach the brethren. Would it not be a good plan to give up and not try to teach any more until I could set a better example? I am afraid if I did, that there would not be any more Home Papers. Well, what is a body to do? Why, the Master indicated plainly—straighten out the wrinkles, soften down your face, look pleasant, and pretty soon everybody will know that you are sitting at the Savior's feet like an obedient pupil, and trusting all to him. If he is "in all" (Colossians 3:11), people will believe it a great deal quicker if you show it in your face and your daily actions, than if you stand up and say so in the prayer-meeting.

Just at this present time, if I am not mistaken, there are quite a number among the readers of GLEANINGS who are "cumbered with much serving," besides myself; and in my efforts to help these friends, after having read the letters they have written me, I have felt most vividly that we all of us need to remember more that one thing needful. Quite a number of the brethren have invested more largely in business than they ought to have done. During the fore part of last season there seemed a prospect of a great demand for many things, that did not hold out as we expected; and after the honey season was over, we found ourselves with unsold property on our hands, and debts to meet. Some of us have had "too

many irons in the fire," to use a common expression. We, by our anxiety to accumulate wealth and business, cumber ourselves, and we have been working and worrying until we have hardly time for the weekly prayer-meetings, for the Sunday-school lesson-helps, for Bible-reading, and the study of God's word. We have been following Martha's plan, and we have not been happy.

Years ago a little brother stood by my side. He was as bright and as pretty and as funny as Huber; and with the rest of the children I taught him to walk, and laughed at the efforts of his baby-tongue to frame words and sentences. I personally taught him his A B C's, and led his little infant mind through the First Reader. He did not take naturally to study; and when he was tired I used to take long walks with him in the fields. Sometimes I took him to the neighboring grist-mill, and let him see the "wheels go round." Happy days those were; and since that brother has grown up and gone into business, I often think of him. He was always industrious and hard working, patient and faithful, and yet I fear his life is not as happy as it was when he was a lisping child, knowing nothing of the cares of this world. One reason why he has had so much care and worry is, because he has tried too many kinds of business. By the time he has become expert and efficient in one line, he has taken some other, and has had to learn a new trade as it were. Of course, there has been reason for this, and good reason. When his health failed from indoor work, he turned to farming; but I think he commenced on too large a farm. Boys, how many of us are doing that same thing? Instead of being content with a little of this world's goods, and that little in such good order, and so well cared for, that it does not cumber us, and make slaves of us, we cripple ourselves by taking upon us too much care and too much worry. I need this little verse, may be, more than any of you, and I am going to try to profit by it.

There has been quite a protest of late against crowding children at school, especially while they are young. Our boys and girls often have more studies than they can manage easily. They become burdened and cumbered, and very often, I fear, the one thing needful is crowded out or passed by for the time being. Now, it is not only the children, but it is men and women in early life, that are cumbered, cramped, and crippled by cares too heavy for them, and burdens too great. A few days ago I had a talk with a young man who has commenced lately in business. He is bright, active, ingenious, honest, and true. Besides all this, his physical health is good, and he is in love with his chosen avocation. I used to look upon him as a model, almost, of a nice business young man. I felt sure he would win his way in the world, and it seemed to me as though he had the mental and physical ability to rise in the world easily. It used to be worth a good deal to me to see him laugh over his work, especially when he met obstacles. He was always cool and quiet and collected; but for all that, he enjoyed a suc-

cess and a victory over obstacles as much as anybody. Well, business sort o' fell in his way as it were; in fact, it tumbled into his hands, as business always tumbles into or on to those who are capable, brave, and true. I saw, or thought I saw, with dismay that he was going to have more than he could well manage. It was business of such a sort, too, that there was no margin to pay for efficient helpers. He came to me for a little advice on some matters connected with his business. I told him how I felt about it. Finally, said I, "Do you enjoy your work? are you as happy in carrying it on as you used to be when you had only a little, and that little was always nicely done, and easily under your complete control?"

"No, I do not enjoy it one bit," was his reply.

He is a Christian, and fully understands all these things I have been telling you; but I fear he is getting to be "cumbered with much serving," like so many of the rest of us; and if he is not released from some part of the weight that rests on his young shoulders, I fear he may be crippled for life. I do not mean by this that his health will break down, but I am afraid his natural fund of courage and energy, and also his rare skill and ingenuity, will be drowned in drudgery and toil too great for one of his age. I do not fear that he will lose his hold on Christ, but I am afraid his life will not be as happy and joyous and as useful in the work of the Master as it might otherwise be.

I want to enlarge right here on a point that has been a long time on my mind, dear friends. It is this matter of taking upon ourselves, or loading upon our children, more than they are ready for or can bear. You know how often I have recommended that beginners in bee culture should take a few hives—one or two; and when they become perfectly able to take charge of more without being cumbered, then let them do it. It is true in any kind of business; and I do not know but it is true in all animated nature. Peter Henderson says, if a plant gets feeble, and looks as if it were going to die, do not put on guano or liquid manure; do not even water it; let it alone. When the soil is so dry that the plant looks rather dried up, it will very likely start to put out a leaf. Now, if you make haste to give it a dose it will surely die. Give it a very little water, and watch the effect. When you find that a little water causes it to thrive, increase the quantity a little, and do this so carefully that you will, after a little, discover how much it will bear. When you begin giving it fertilizers, work in the same way. First satisfy yourself what it will bear, then feed it just so much as does it good—no more. In due time you can turn on the water by the barrelful, give it wheelbarrow loads of strong manure, pour on your liquid fertilizers without stint, for it has become now a great tree, and can manage strong food. The plant thrives, and looks happy. You are happy too, because you have learned to understand it. The same is true of sick people or sick animals. Wait until you know that what you are giving does good be-

fore you give it too heavy loads or heavy doses.

Can a man be a Christian, and yet be unable to meet his honest dues? Why, yes, of course he can, for Christians are often beset with unseen reverses; but I tell you, my friends, a Christian can work for the master tenfold more effectively if he can be free from these kinds of encumbrances, and he ought to be very careful that he does not get into any places that will cripple him and cumber him, and weigh him down in the way debt does. Now do you see my application? When you go into business, have a little business, and have that little nicely attended to. Have your shop and your tools all decent and in order. Be so much abreast of your work that it will not suffer if you take an hour or a day to sit at the Master's feet, or to do errands for him when he bids you. When you can manage easily without being cumbered, and feeling that your work is drudgery, then, if you choose, undertake a little more, or enlarge somewhat.

But I do think, dear friends, it is a most excellent thing to have some hard cash ahead. Mr. Terry has written an excellent article in the *Ohio Farmer* recently, on this very subject. He said that he once had an accident that came near taking his life. He was too badly hurt to speak, or give any sign to let them know that he knew what was going on around. But even at such a time it gave him a thrill of pleasure, and he thinks helped toward his recovery, to remember that there was money enough in the bank to meet all his obligations, and pay all expenses attending a spell of sickness. Mr. Terry is a farmer. He makes farming pay; but after reading his articles for some time past, I have come to the conclusion that one great secret of it is, that he is never cumbered with much serving. He has not only time to do every thing that needs to be done, and to do it well, but he has a little spare cash always on hand to meet any contingency, or to take advantage of any rare chance that comes along. I do not know that Mr. Terry is a Christian, but I do know and feel that he sets a good example for Christians.

A few days ago it all at once occurred to me that this young brother of whom I have been speaking was in danger of going through life without enjoying the things that God has placed here in this world to make us happy. He is a farmer, and has a large beautiful farm, if I am correct; but with the amount of business he always has on hand, and which he is unable to attend to without expensive hired help, I am afraid that life to him will, on the whole, be a sort of weary slavery of business, instead of being glad and joyous, as God intended it should be. A few days ago he told me if his last venture did not succeed any better, he was going on to his farm with his boys, and that he would not have a bit of hired help around him. What they could not do should be left undone, and they would take things easy. It seemed to me like a bit of bright sunshine coming out through the clouds, and I decided I would take a part of the advice myself.

Now, why is it that we voluntarily cumber ourselves with so many cares? I have thought of this matter a great deal. As a general thing, I believe we cumber ourselves because we hope to make much money by some new investment or industry, or we hope to make money easier than we have been doing. Some of us get tired of the monotony of every-day life. We want something new—some sort of excitement as it were. The Root family are especially subject to such feelings, I believe. If they do not have some sort of excitement going on, they imagine they are sick—at least that is my disposition a good deal.

And this brings us to our text again—what do we desire most in life? and is the thing we desire most, the one thing needful? When Christ is first and foremost, and when we get up a healthy excitement in regard to living pure lives, then we are all right. Now, suppose we should get carried away with the idea of doing justly, loving mercy, and walking humbly before God, what harm would it do? Or suppose we should get up such an enthusiasm that we could hardly wait for daylight to come, and, in a determination to stop expenses, make the best of every thing we already possess, owing no man ought but love and kindness, and things of this sort, would anybody be afraid that we should carry it to too great an extreme? I am fond of excitement; fond of new hobbies; but if I do not look out it runs into a fondness for buying new and expensive machinery, new and high-priced seeds, strawberries, raspberries, poultry, etc. Well, during the past few months I have been very happy in a new idea of taking good care of the property *already* in my hands, and a blessing has come with it. It seems to me it is a good deal like my brother's decision to go on to his farm, without a bit of hired help, thus stopping outgoes, do the best he could, working alone with the children God has given him, and accepting such reward as God chooses to give, and *make* expenses come inside of this reward. Does not this come pretty nearly in line with our text? One who does this can look to the Savior, and sit at his feet with a clear conscience, and the happy, peaceful sense of wronging no man. When some money is put away for sickness and a rainy day, and the lesson has been well learned, of making expenses keep inside the income, then let us wisely and carefully consider new seeds, new stock, new machinery, etc. In carrying this out, perhaps we may go through the world poorer in dollars and cents than by taking risks and incurring debt, (I can not for a minute think it possible, however, in a general way; can you?) but shall we not be richer in that good part which shall not be taken away?

Now, friends, how shall it be? Will this next venture that stands right before you cause you to be "cumbered with much serving," spoil your happiness and peace of mind, or will it lead to a low seat at the Master's feet, with kindness and good will toward men? Is Christ the Savior first, foremost, and all in all to you? or are you so far from him that the cares of the

world stand between you and cumber you? Are you serving him with a joyous service, or are you a slave to this world's cares, cumbered and bowed down? If the latter, in his name I bid you drop it all. Come, and let us take a low seat near to his feet, and learn of him, for we have the promise, "Seek ye first the kingdom of God and his righteousness, and all else" (these things that cumber and worry us included) "shall be added unto you."

RECENT DEVELOPMENTS.

And Suggestions and Queries Particularly Pertaining to the Season.

FEEDING AFTER NOVEMBER, ETC.

JAN. 1, 1884, I began giving my whole time to the bee business. They did well the first two years, some making 100 lbs. of surplus, which I sold at 20 cts. at home; but this year was a "stunner;" white clover did well for us, but it has not got well set in our country yet. After that there was very little. Blooms were very plentiful, but had no nectar. I made 35 chaff hives on my Barnes saw. I bought bees and filled 20, and with my 10 old and 6 new ones made 26; they were all in good shape for our fall bloom, which is the crop here. In 1883, the 12th of Aug. was the first surplus I got. The flow lasted till Sept. 15th; but this fall I was feeding, instead of taking off surplus. Owing to sickness I was delayed feeding till November. I was bothered a good deal in not having a larger feeder than your five-cent one. My bees had only 5 to 10 lbs. when I began, so I fed 10 lbs. of syrup, of granulated sugar, half as much water as sugar; then I saw Jas. Heddon's article on syrup, only 3 lbs. of water to 10 of sugar, and a little tartaric acid. This made a syrup so thick that on cool nights it would be taken down very slowly. I tried making 50 lbs. into candy in brood-frames, as A B C tells of, and much prefer it to syrup so late as this. It was hard to get chaff to put in upper story, so I went to the corn-sheller and got the silk that is cleaned from the shelled corn. What do you think of it?

Hopkins, Mo.

JOHN C. STEWART.

The silk from corn answers nicely in place of chaff, friend S.; but you wait to look out for mice. They think it is nice too. I think I should prefer candy so late in the season.

DRONES IN THE WINTER.

To-day, Dec. 23, I have a colony of bees with nice drones. I should like to know the reason. They have a nice queen. I got her from you last October. They have had drones since June, and have had them ever since the rest killed their drones last July. This one has quite a lot. CHAS. SAYLER.

Marchand, Ohio, Dec. 28, 1884.

As a rule, drones in winter indicate the queen to be a drone-layer or a partial drone-layer, although this is not always the case. Sometimes a very strong colony will keep drones right through winter, without our being able to observe that the queen is in any way lacking when she commences laying largely in the spring. If sealed drone-brood is now found in the hives, I should be inclined to call the queen a drone-layer.

CALIFORNIA HONEY AT 12½ CTS. PER LB.

The following came to hand after our regular market report had been printed:

CHICAGO.—*Honey.*—The demand is very light. Prices are weak, and a gradual decline of prices will follow this date, in the effort to work off the crop. Many of the producers are yet in possession of their last crop. California honey can be bought here at 12½c per pound in comb.

Chicago, Ill., Jan. 12, 1885.

R. A. BURNETT.

MOVING BEES WITH HOUSEHOLD GOODS.

I moved 12 colonies of bees in a car with household goods; car was 8 days on the road. Bees were shut up 12 days in Langstroth hives, with wire screen on top. Result, about one quart of dead bees in every hive; about a dozen broken combs, queens safe, and colony in fair condition for wintering.

Bolivar, Denton Co., Texas. GUSTAV RAUCH.

FROM 3 TO 16, AND A PLEASED "PASSENGER."

Being very well pleased with your "craft" and its crew on the voyage last year, I have concluded to renew my ticket, and keep company with you through the present year. Find the "ducat" inclosed. I lost more than half my bees last winter, with dysentery, and the remainder were weak. I did not get an ounce of honey last season, running alone for colonies, ending the season with 16 from 3. I have them packed in paper, on a plan of my own, which I may describe to you, should it prove a success. If not, the less said the better. They went through the late cold snap finely, and yesterday were out strong, making good use of the present warm spell.

C. GARWOOD.

Baltimore, Md., Jan. 1, 1885.

MY REPORT FOR 1884.

Last spring my bees were in pretty fair condition, being strong in bees, honey, and brood, when the yield of honey commenced, all except 4 that were weak, and did not make any honey, only enough to keep them, and for winter. From the 53, I secured of surplus honey, 320 lbs.; 1900 lbs. in one-pound sections; 800 lbs. was all I got finished from clover and basswood; the rest was finished with Spanish needle and smartweed honey, which looks very nice in one-pound boxes. I had 1400 lbs. of extracted honey, mostly fall honey. My increase was by dividing and building up, and rearing queens. Nearly all were in pretty fair condition for winter.

SHOVELING SNOW OVER THE HIVES.

There was a pretty good snow last Tuesday, and I shoveled snow over all the hives, thinking it would be cold weather for a month or so; but I was disappointed, for the weather is warmer, and has been raining for almost a week, and to-night 'tis just pouring down. The snow is all melted, and the ground is all covered with water and mud.

Lima, Ills., Dec. 20, 1884. J. A. THORNTON, 51-73.

Friend T., I do not believe I would shovel snow over the hives, neither would I shovel the snow off, as some of the friends have done. This is an old question, and I believe the general decision was, not to do any thing with the snow at all. If you could fix up some sort of a windbreak, to make the snow drift up over the hives, so as to be soft and light, just as it falls, it would be an excellent protection; but shoveling snow is apt to disturb the bees, and may do them harm. In fact, examples have been given, showing pretty clearly that unreasonable disturbance sometimes results in dysentery.

FEEDING BEES.

LAYING CANDIED HONEY DIRECTLY ON TOP OF THE FRAMES.

LAST winter I fed honey in the cellar, that was candied hard; it was good clover honey. I broke it in chunks of about one or two pounds, and laid it on top of the frames. They took and put it in the cells, and sealed some, and some of the bees built comb on top of the frames, but the honey needs to be candied so solid that it will be almost like candy made of sugar.

WORKER-BEES FROM A FERTILE WORKER.

Did you ever hear of a fertile worker producing worker-brood? Well, I had a stand that I divided about the time the honey-flow ceased. I took the old queen away and gave them a cell which they cut out, and then started cells of their own in due time (almost 7 days). I shook off all the bees, and destroyed all the cells. I went over them again in two days, and took out every thing that was capped higher than a worker-bee, all drones, and gave them two cells which they destroyed in a few hours. I then thought I would give them a caged queen in a day or two; but in a day or so, when I looked into the hive I found a few eggs, and in a few days they had four combs filled irregularly with eggs, and some would have as many as a dozen in, and others a less number. Well, I hunted three days, and found nothing that laid eggs. I shook them out in some smartweed, away from the hive, and let them go back when they got ready. I have sometimes got rid of fertile workers in that way, but it did no good. I tried queen-cells again, but they cut them out, so such work went on for two weeks, when they had five combs of brood—sealed drones in worker-cells. I carried the hive to another one, and shook the bees in and put in three combs of the brood and two combs of it with another swarm. I then closed up for that day, as robbers were flying around. The next day I went out with my knife, and clipped the drone-heads off in a hurry from all the combs, and was not very particular in missing a few. In two or three days I went again to make another examination of the combs, and shave off the remaining few little drones. I got through at one hive, and went to the other. I began to shave again, when I pulled out some young worker-bees that had got their wings, and were perfect. I almost finished, but found three in cells that I had not yet reached with my knife. I went to the first combs and found two more among the wonderful lot of drones. You will perhaps doubt. Well, the above is correct and true; and if I could see you I could tell it better than I can write.

Cascade, Iowa, Dec., 1881.

MONT. WYRICK.

Friend W., your plan of feeding candied honey has been mentioned before; but the difficulty seems to be to get honey that will candy hard enough. In regard to the worker-bees from fertile-worker brood, it seems you must have made a mistake, and got hold of the wrong combs somewhere; but, of course, you know better than we do whether or not this were possible. Young queens often lay drone-brood for quite a spell, or until they have filled several combs, and change to worker brood. Is it not possible that a queen got into your hive and laid those eggs, or a portion of them, that you thought were laid by fertile workers?

HUMBUGS AND SWINDLES

PERTAINING TO BEE CULTURE.

THE BOHEMIAN OATS; AN OLD AND EXPLODED SWINDLE.

MR. A. I. ROOT:—I don't like to draw your attention from your business, but I will tell you why I write to you. There are two men in this county, hailing from the northern part of this State, who claim to represent the "Bohemian Hulless-Oats Association." I tell them that their scheme is a fraud. They refer me to several northern counties where the "association" has "operated," and say the farmers are well satisfied with the "operation." One of the counties is Medina, and perhaps you know something about the scheme. Several of our best farmers are buying oats of them, paying \$10.00 per bushel, expecting big profits back. I am a farmer, and a beginner in bee-keeping. I love to work with bees, but I don't want any oats at \$10.00 per bushel. I am well pleased with GLEANINGS.

Very respectfully yours,— T. L. REES.

Winchester, Adams Co., Ohio, Jan. 7, 1885.

Friend R., the Bohemian hulless oats is one of the biggest swindles that ever cursed Medina County, and the same may be said of the whole of this part of Ohio. In our vicinity the whole thing is now an old and exploded humbug. If you want further particulars, see the articles on this subject in the *Ohio Farmer* of late. You or anybody else can buy as many genuine Bohemian hulless oats as you want, for about 75 cts. per bushel. If your best farmers are, at this late day, going into that miserable, foolish fraud, they are behind the times. Some men have made money out of it, no doubt; but in so doing they have robbed their neighbors, or innocent men who will have to bear the loss eventually, for the loss must come sooner or later. Honest, hard-working people who will sell their influence and reputation for the sake of the little money they get in their pockets by the operation, ought to be ashamed of themselves. Surely, no Christian man would keep money in his pocket thus obtained, after he had seen the way in which innocent parties are made to suffer.

BEES IN INDIA.

A MISSIONARY'S ACCOUNT.

IRESIDED seven years in India as a missionary. My home part of the time was in the Himalaya Mountains, about 1100 miles northwest from Calcutta, east from Hurdwar. I hope to start for that country about Dec. 1, and make a permanent home there. I expect to introduce a number of industries among the native Christians; and as there are plenty of honey-bees in the rocks and trees, and they even come into the native houses and store their honey, I hope to get the busy bees to do some mission work. I never saw a bee-hive there, or a pound of honey, except what the natives cut from the trees. Bees are plentiful, and bee-food in abundance, and the season lasts from eight to ten months. The altitude will be 3000 to 5000 ft. above the level of the sea, and the latitude about 30 or 32°.

The bees could not be placed in the open air there because black bears are plentiful, and the human thieves too numerous. I do not know what kind of bees are there as I never observed them.

Evanston, Ill., Oct. 16, 1884.

I. L. HAUSER.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,

EDITOR AND PUBLISHER.

MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clipping Rates, See First Page of Reading Matter.

MEDINA, JAN. 15, 1885.

And nothing shall by any means hurt you.—LUKE 10: 19.

HOLTY-TOITY! What do you think? We have got some of the seeds of the *Epilobium angustifolium* already up in the greenhouse. The plants are very small—microscopic almost, but we've got 'em. Aren't you glad?

DISCOUNTS BEFORE FEBRUARY 1.

ON sections, foundation, and foundation-mills, we still allow a discount of 10 per cent. We also sell 10,000 Simplicity sections for \$40.00 as heretofore. We continue these offers, as we have a large stock of the above goods in stock, and are anxious to supply as many as we can before the great rush comes. We will also allow a discount of one per cent on orders of every description, received before Feb. 1.

OUR TEN-CENT POULTRY-BOOK.

By buying in large quantities, I have been enabled to get a very pretty little poultry-book of 48 pages and 19 illustrations, that we can sell at the very low price of 10 cts. The book is well written, and covers nearly all that is important to success, and does not puff any patent medicine. One cent extra for postage, if wanted by mail. In the above book I am especially pleased with some of the cheap designs for poultry-houses, such as almost any boy can make in the corner of the dooryard. The book is usually sold for 25 cents.

INK BY MAIL AT 15 CTS. PER PINT.

MAY be you all say that can not be, because the P. M. G. will not allow it. But you see we are ahead of you. Friend Oldroyd has contrived some ink-powders that will make just as good ink as he ever made in the world, simply by dissolving the powders in water. Each package, dissolved in a pint of pure rain water, makes a pint of good ink, and the price is 15 cts. If wanted by mail, add 2 cts. per package. We have in stock, packages for black, blue, violet, green, or red. Eight packages will be sold for \$1.00, or 60 packages for \$5.00. If it ever gets too thick, it can be reduced any time with water. They will not injure by freezing, and do not corrode the pen.

SOMETHING ABOUT OUR ONE-PIECE SECTION MACHINE.

We have made such improvements that we think we have the best machine in the market. On our old machines the collars that the saws were fasten-

ed to were held in place by set-screws; but we found they sometimes slipped, and thus made bad sections; and more than all that, constant tightening would spring the shaft; so we made a shaft with a thread running the entire length, also a thread in collar, and a nut to follow collar, and now we have no trouble to set saws or cutters, and have them stay. We have also made improvements in the feed motion, doing away with the screw, or worm, to reduce the motion, and reduce it by means of counter-shafts and pulleys. Our crank-shaft is now horizontal, having a crank at each end, thus giving a more steady motion to the table. We have also added a planed iron plate that is placed under the cutters, so when once set as wanted it will always be true. We can furnish machines to make V or square grooves, at \$90.00. This is \$15.00 more than our old machine, as per former price lists.

WHEN DOCTORS DISAGREE, WHO SHALL DECIDE?

In our December number, page 859, Gen. Leggett declared that Forncrook had not then taken an appeal. Mr. F. sent us a statement from his lawyer, declaring the appeal to have been taken, and that the clause in Forncrook's price list was fully authorized. I am sure I do not know who is right in the matter—perhaps both are right—Forncrook meaning that steps had been taken to take an appeal, and I think Gen. Leggett was certainly correct in saying that Mr. F. had not taken an appeal. Mr. J. A. Osborne, who had charge of the case, writes that on the 6th of Jan., Forncrook filed a bond with the clerk of the Circuit Court, for the purpose of taking an appeal, and I am to-day, Jan. 6th, officially notified that such an appeal has now been taken. I do not know that it makes any very great difference when the matter is commenced, more than that, if any statements have appeared in GLEANINGS not strictly true, it was because we were wrongly informed; and whenever we are satisfied that we have been wrongly informed, we are always ready to retract.

OUR NEW MACHINE FOR MAKING THE FOUR-PIECE DOVETAILED SECTIONS.

WE shall probably soon have an engraving of this machine, to answer the many inquiries in regard to it. It may be described briefly thus: Imagine a ten-inch circular saw properly hung on a mandrel, directly before your face. Well, now, right under the saw imagine a wooden wheel covered with sandpaper. Suppose both saw and wheel to be running at the proper speed. In front of the sandpapered wheel is a table. On this table you lay your piece of planed plank, dovetailed, of course, on each end. Now, if you lay a piece of plank on this table, and push it up against the sandpapered wheel, of course the face end of the plank will be sandpapered. Well, the table on which the plank rests is attached to a frame like the frame of an old-fashioned up-and-down water saw-mill. By means of a crank and pitman, this gate has a slow motion up and down, carrying the table with it. Now, this sandpapered wheel stands a little further back than the buzz-saw—just enough back of it so that when the plank is carried up after being sandpapered, the buzz-saw slices off a piece just thick enough for a section blank. After this blank is sawed off, the table falls until the blank stands once more in front of the sandpapered wheel. Just as soon as it comes in the right position, the operator crowds the plank forward, sandpapers the end as before, and the

buzz-saw slices off another blank, and so on. The machine is quite simple, and does its work perfectly. We can fill orders on short notice, for \$30.00 for a complete machine. This machine will make about 8000 or 10,000 sections per day; and as it dispenses with the cigar-box planer (the sandpaper wheel taking its place), it is the cheapest rig, perhaps, for making sections, all the machinery needed being an ordinary buzz-saw table and set of groovers. Of course, you will need a planer to plane the plank, unless you have it done at some planing-mill.

OUR TEN-CENT INDUSTRIAL LIBRARY.

A BOOK on horses. We have just made arrangements whereby Kendall's treatise on horses can be furnished for only 10 cts. We have sold hundreds of the books for 25 cts., as many of the friends will remember. This, with the poultry-book mentioned elsewhere, makes two toward our ten-cent industrial books. We expect to buy these books by the thousand, and therefore we ought to have a pretty fair little treatise on matters in special rural industries for the above amount of money. If wanted by mail, add two cents extra for postage.

FILING GROOVING-SAWS.

In my remarks in regard to the matter last month I omitted to state that these should be properly adjusted on the mandrel, with the necessary washers and papers to make the dovetailing as tight as you want it; and after being so screwed up, the saws should be filed right on the mandrel. Under no circumstances think of filing them separately. If you once get the adjustment changed, it is next to impossible to get them in place again. Always file gangs of saws right on the mandrel. Our cant files on the different counters are right for the purpose.

AN APOLOGY FOR AN UNINTENTIONAL BLUNDER.

I AM ashamed to say it, but quite a number of cast-iron hammers have been sent out where steel ones were ordered, and should have been sent. They are worth 15 cts. each, while the steel ones are worth 35 cts.; and therefore if any of the friends who have received them can make use of them so as to allow us 15 cts., we will give them credit for 20 cts. on account, if they will notify us of the fact. If that won't make it pleasant, tell us what to do, and we will try to do it. The fault was with the manufacturer who shipped us the hammers; but as he failed in business soon after they were sent (is it any wonder?) it seems I have nobody to fall back on. When the matter was submitted to me I remonstrated because the clerks did not know by their looks what the hammers were. They said they knew they did not look just right, but supposed they must be, because they came out of the right box. We found three dozen of these hammers mixed in among a gross of steel ones.

ADVERTISING YOUR BUSINESS.

MAY be you think by the above that we are fishing for advertisements for our journal. Well, just see now how much you are mistaken. What I had in mind was some little sign-boards to tack up on the gate-post, or on the barn, or may be on a tree. In fact, you can put them in all these places if you wish, and you won't be much out of pocket then, for they cost only 10 cts. each, and yet they are $4\frac{1}{2}$ inches wide and 18 inches long, and are very prettily lettered, "Honey for Sale." They are, in fact, an improvement on the sign-boards advertised in our price list. But they are made by a new process. They are, in fact, printed on a large printing-press made expressly to print sign-boards. The only way

I could buy them so as to sell them at this extremely low price was by buying 1000 "at a lick." Now, you see, I can not get my money back unless I sell an "awful lot" of them, and that is what's the matter. If you want them by mail, add 6 cts. for postage and tying them up.

REVERSIBLE FRAMES.

NIMSHI NUZUM, of Boothesville, W. Va., has sent us a model of the best device for a reversible frame, in my opinion, of any thing heretofore presented. I should say there was no question but that it would work, and the expense need not exceed two cents per frame. In fact, we will agree to furnish them for that, and I think likely they can be furnished for less, with proper machinery. It is made from a single piece of tin, by cutting and folding, without any solder, and yet it is strong and substantial when finished, like the device in the last volume, page 156. Friend N.'s device, with appropriate engravings, will be given in our next issue. We will furnish reversible frames, made on this plan, for \$5.00 per 100 in the flat, or \$6.00 per 100 put together and wired. Sample by mail, 15 cts.

P. S.—Dear me! who shall say again what can or can not be done? Our friend M. Broers, of Gonzales, Texas, sends us a reversible metal corner that beats friend Nuzum's, and all that have heretofore appeared. It is strong and simple, and reverses without any loose traps. We can furnish them for one cent each, and they can be put on any frame in a moment. This is the best thing at present writing, but no one knows what the next mail will bring.

CIRCULARS RECEIVED.

- J. S. Tadlock, Luling, Texas, sends us a 4-page circular.
 B. J. Miller & Co., Nappanee, Ind., send us a 12-page list of hives and supplies generally.
 Kennedy & Leach, Higginsville, Mo., send out a 6-page circular. Hives, and supplies generally.
 E. L. Gould & Co., Brantford, Ontario, send out a 40-page circular, giving much valuable information.
 F. Boomhower, Gallupville, N. Y., 12-page circular, printed at this office, and contains much useful information.
 Drake & Smith, successors to A. E. Manum, Bristol, Vermont, send out a 12-page circular, specially, white-polar sections.
 A very pretty 4-page circular, printed at this office, for A. F. Stauffer, Sterling, Ill. Specialty, chaff and Simplicity hives, Italian bees and queens.
 The H. F. Moeller Manufacturing Co., Davenport, Iowa, send us a 28-page circular of hives, and supplies for beekeepers generally. This firm also manufactures washing-machines.
 F. A. & H. O. Stillbury, Geddes, N. Y., send out a very pretty 22-page price list. One of their specialties is the Shipman automatic engine. It needs no engineer nor fireman, but runs by kerosene-oil.
 Friend Heddon sends us a very pretty 32-page catalogue, full of much valuable information. In it his new reversible frame is illustrated. This accomplishes the object completely; but you can not use the frames already in use, unless you enlarge your hives, or something of that sort. Friend H. does not advertise pure Italians or pure bees of any kind, if I am correct, but advertises a cross between the common bees and Italians. He has been for some years working with a particular strain. I should not be very much surprised if it were true that a good strain of hybrids will give better results, taking all things together, than pure Italians. Friend H. will certainly have one comfort in sending out queens: nobody can ever complain of him that he sent out hybrids.

FOR SALE OR EXCHANGE.

I have the following goods on hand, that I will sell cheap, or exchange for any thing useful to me. Fourteen second hand Pianos and Organs, six Sewing-machines, new, a large quantity of Sheet Music, and Instruction-books. Also, small instruments. All are the stock of my discontinued music-store.

VANDERVORT COMB FOUNDATION MILLS.

Send for samples and reduced price list.
tfdb JNO. VANDERVORT, Laceyville, Pa.

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or \$2.00 per year.

\$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or \$2.00 per year.

Those whose names appear below agree to furnish Italian queens for \$1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable. Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for \$1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey.*—Very little honey being received, and stock of 1-lb. sections about sold out. The stock of 2-lb. sections, California, is good and very low, while the low price of 2-lb. sections keeps 1-lb. sections low also. One-pound sections, 15¢@16¢ for good white comb in good style of crates; 2-lbs., 12¢@14¢; dark and old stock, 8¢@12¢. Extracted, California, 5¢@6¢; white-clover, 7¢@8¢; Southern, 5¢@6¢. Trade is looking brighter. *Beeswax*, none in market. **CLEMONS, CLOON & CO.,**
Jan. 22, 1885. Cor. 4th & Walnut St's., K. C., Mo.

CINCINNATI.—*Honey.*—The market for honey in all its branches was extremely dull with us since our last report. Manufacturers buy but little, and jobbing trade is slow, while retail demand is only fair; offerings are liberal of comb and extracted honey at prices at the option of the buyer. No change of quotations from last month. *Beeswax* is in good demand, and offerings are fair. It brings 26¢@30¢ on arrival. **CHAS. F. MUTH,**
S. E. Cor. Freeman and Central Avenues,
Jan. 26, 1885. Cincinnati, O.

CHICAGO.—*Honey.*—Market very quiet. Prices easy; stock heavy. California takes preference in the home demand. The cold weather does not permit of shipping at present, if there were any orders; but I don't know of any orders here this week. Extracted, very dull. *Beeswax*, 30¢ for yellow. **H. A. HURNETT,**
Jan. 21, 1885. 161 So. Water St., Chicago, Ill.

ST. LOUIS.—*Honey.*—No change to note since our last report. We quote to-day as follows: Southern extracted honey, in barrels, 5¢@6¢; half-barrels, 6¼¢. Northern, worth more. There is only a retail demand for comb honey. White clover, 15¢@16¼¢. Dark not wanted. *Beeswax* dull at 26¢@29¢. **W. T. ANDERSON & CO.,**
Jan. 26, 1885. 104 N. Third St., St. Louis, Mo.

BOSTON.—*Honey.*—Honey, very slow of sale; 15¢@16¢ for best white 1 and 2 lb. sections. Extracted, no sale. **BLAKE & RIPLEY,**
Jan. 21, 1885. 57 Chatham St., Boston, Mass.

DETROIT.—*Honey.*—The honey market is but fairly active. A good article is bringing about 14¢. **A. B. WEED,**
Jan. 21, 1885. Detroit, Mich.

FOR SALE.—I will sell honey in any sized cans (cans included) at—white clover, 11¢; buckwheat, 9¢; 1500 lbs. on hand. **H. BARBER, Adrian, Mich.**

FOR SALE.—600 lbs. white-clover honey in 1¼-lb. sections. **JOHN F. RACINE,**
Wallen, Allen Co., Ind.

FOR SALE.—500 lbs. of choice white-clover honey. Very light color, extracted. Who wants it, all or part? **WILL ELLIS,**
St. Davids, Ont., Canada.

FOR SALE.—I have for sale about 6 tons of honey in 5-gallon tin cans, put up in cases, two cans in a case. Also about one ton of comb honey in 1½-lb. sections. **C. S. LEWIS,**
San Jacinto, San Diego Co., Cal.

FOR SALE CHEAP.—500 or 600 lbs. of white-clover and basswood honey, in 1 and 1½ lb. sections, for one shilling per lb., delivered on cars here. **G. W. ALBRECHT, Dundas, Calumet Co., Wis.**

RASPBERRIES AND STRAWBERRIES FOR 1885.

Ohio, Souhegan, Tyler, Gregg, Cuthbert, Hansell, Crimston Beauty, Shaffer's Colossal, Raspberries; James Vick, Manchester, Sharpless, Wilson, Crescent, Chas. Downing Strawberries, and many other varieties not mentioned here. **PRICE LIST FREE.**

the U. P. C., 42c per year extra.

NOTES FROM THE BANNER APIARY.

NO. 62.

BOILING SUGAR SYRUP.

FRIEND ROOT:—You say, on page 6, that you are glad to know that I succeeded in making feed without boiling it. I *succeeded*, but the feed *crystallized*. Unless the feeding were done early enough for the bees to work it over and seal it up, I should certainly boil it. Almost every one who is in the bee business very extensively has a shop, and in that shop there is a stove, and upon that stove the feed can be made with no annoyance to the family.

HEDDON FEEDERS AND WARPED COVERS.

No, I didn't purchase my feeders and covers of Mr. Heddon, but made them myself from samples obtained of him. Will you pardon me, friend Root, if I say, that to one who has for two years used the Heddon feeders and covers, the manner in which you cling to the idea of warped covers is almost amusing? There is no trouble in buying lumber that is not warped. This lumber can be planed perfectly true and smooth at a planing-mill. Now, then, does it require any great mechanical skill to saw the lumber up into the proper lengths for covers, nail a cleat to each end, and paint the cover? On page 47 you say: "During the convention it was made plain to me for the first time why people wanted this honey-board." Perhaps you are also at sea in regard to the cover for the Heddon feeder. This view of the matter is further strengthened by your concluding sentence in the reply to Mr. Heddon's article on page 9, in which you speak of the "stiff rim to hold the cover-boards from warping." Friend R., the cover has no rim.

DOOLITTLE'S COMMENTARY

On page 51 is, so far, all right. In fact, it appears to me to be an enlargement and explanation of my article. Some of the explanations and reasons given by Mr. Doolittle appear to me as superfluous, being almost self-evident, as it were, while others are quite important. I shall look forward with interest to reading the remainder of his comments.

SIZE OF SECTIONS, AND MORAL PATENTS.

Friend Hutchinson:—I have been thinking I would write you once more on the section subject, but have not found time until now. Since you published my letter, and replied to it in GLEANINGS, a bee-keeper from Mauston, Wis., has visited me, and we had quite a discussion on sections. His crop this year was about 10,000 lbs. of comb honey; it was stored in sections $4\frac{1}{4} \times 5 \times 1\frac{1}{2}$, and he likes that size very much. He says they weigh exactly one pound each when filled in the Heddon case, or something similar, and that the extra length causes them to be ripened and finished sooner than the regular size. He says that a $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$ section will *not* weigh a pound; and if you look at Mr. Heddon's circular, p. 20, you will see that Mr. H. says so too. "When doctors disagree, who shall decide?" Have you tried it *yourself*? I want to make my cases for next year, and how to make them is the question. Don't you think the $4\frac{1}{4} \times 5 \times 1\frac{1}{2}$, on account of its larger surface for evaporation, is the one to adopt? Then it *looks* larger, thus having an advantage in selling. If we are to use the case method, why cling to the old size of section, whose only merit is in just filling an L. frame? The larger size will cost no more, and I think would be stronger to ship.

What do you think of Mr. Heddon's closing paragraph in his article in GLEANINGS for Dec. 15? Does that not savor of monopoly? It seems to me he is putting a sort of moral embargo on us, that, if carried out, would amount to a moral patent, without any of the expense of a real Government protection. It hits me right at home, as I was thinking of making his style of case to sell next season. I could sell them at one-half his prices, and yet make good wages. Do you think there is any moral wrong in so doing? If I mistake not, you are a Christian, and

I ask you as a brother for your opinion. I should not want to go into any thing that had even the appearance of wrong. Please give me your idea from a moral, not a business, standpoint.

Yours truly,— C. A. HATCH.
Ithaca, Richland Co., Wis., Dec. 29, 1884.

To the above I replied as follows:

I have used 4000 $4\frac{1}{4} \times 4\frac{1}{4} \times 7$ -to-the-foot sections, and they will not weigh a plump pound; but it is so near a pound that I did not hesitate in deciding that a section of that size, and plump $1\frac{3}{4}$ wide, would weigh a pound. But, suppose a section *does* lack $\frac{1}{2}$ ounce, or even an ounce, of weighing a pound, what is the objection? It will pass for a pound section, and dealers prefer a section that falls short to one that overruns. I do not, and would not for a moment, cling to the $4\frac{1}{4} \times 4\frac{1}{4}$ because eight of that size fill an L frame, as that method is, I believe, passing away. I cling to it because it is a regular size, and bids fair to become the standard size, and a standard size would be a blessing to everybody. Other sizes may be bought as cheaply now, in most places, but it may not *always* be so, and is not now in some places. Should you ever wish to sell your apiary, it would be more salable if your fixtures were "like other folks'." Were not the sections in your friend's apiary finished more quickly because of their *thinness*, rather than because they were $\frac{3}{4}$ of an inch taller? Are you not mistaken in thinking a large comb will bear transportation with greater safety than a small one?

I do think that Mr. Heddon would be pleased if others would not manufacture his wares for sale, and he has set the example by refraining from manufacturing *other people's* inventions. Did all have such clear ideas of right and wrong as you have, patents would be unnecessary. Were I you, I would write to Mr. Heddon and learn how he feels about it. Can I publish your letter and my reply?

As ever yours,— W. Z. HUTCHINSON.

Mr. Hatch replied as follows:

Friend W. Z. H.—It seems I did not make my meaning clear, for you say: "It must have been the thinness that caused the combs to be finished first." That was just the point I *meant* to make; that is, the extra size would, of course, make them thinner, if the weight remained the same. I give up the other point as to the larger combs standing shipment better. I fear you give me credit for having clearer ideas of right and wrong than I deserve. If you think any good can come from having my letter published, of course you can do so; but perhaps I would have taken more pains in the manner of saying things had I known that my letter would be seen by other eyes than yours.

C. A. HATCH.
Ithaca, Wis., Jan. 8, 1885.

There is no question but that thin combs are more quickly finished, but it does not necessarily follow that the thinnest combs are the most profitable to raise. If eight sections are used in place of seven, the cost of sections, fdn., and manipulations, is increased one-seventh. I see no way in which the question can be settled, except by careful experiments upon quite an extended scale. I have now 5000 section boxes, $4\frac{1}{4} \times 4\frac{1}{4}$ by $1\frac{1}{2}$, and I shall order 5000 more that are $4\frac{1}{4} \times 4\frac{1}{4} \times 7$ to the foot, and I shall select, say, 40 colonies, and upon them use only the sections $1\frac{1}{2}$ inches wide, and upon 40 other colonies I will use only those sections that are "7 to the foot wide." In this manner I hope to throw some light upon the subject of which width is the more desirable. Will others please do the same?

In regard to inventions, discoveries, and patents, I should say that the inventor has as good a right to his invention as a wood-chopper has to his cords of stovewood. Unfortunately for inventors, many of those who would consider themselves disgraced by stealing stovewood, are not troubled with conscientious scruples in appropriating inventions, hence the patent laws and their attendant abuses. There seems to be a growing disposition among bee-keepers to refrain from manufacturing for sale the invention of another, when the inventor is himself manufacturing the article for sale; or, if the in-

ventor does not care to manufacture his invention, the one who *does* commence making it for sale is usually willing to pay the inventor something for the privilege, without putting him to the expense of getting a patent; and when a man thus pays for the privilege of manufacturing for sale, his "right" is usually respected. W. Z. HUTCHINSON, 68—94.
Rogersville, Genesee Co., Mich., Jan., 1885.

BEE CULTURE IN FLORIDA.

A VARIETY OF QUESTIONS, AND FRIEND HART'S ANSWERS TO THE SAME.

MOSQUITOES and sand-flies are seldom very troublesome at Ormond or Daytona, on the Halifax River; very few at Enterprise, and almost none at Orange City, De Land, Lake Helen, and other settlements along Orange Ridge. I think all first-class locations for bee-ranches in this State are troubled more or less by these pests during a portion of the year, but I have never known any one to be entirely eaten up by them, as many of our pine-land neighbors have stated. In fact, after we get fixed for them we manage to live very happily.

At the above places there are quite large settlements of pleasant, intelligent, and cultured people.

We never have such extreme heat here as at the North, owing to the formation of the State, which lies between the Gulf of Mexico and the Atlantic Ocean. It is always comfortable in the shade in summer, and has been so far this winter, as we have had no frost, except in spots.

I do not think biliousness is much more prevalent here than at the North. I have been troubled less in that way here than there. Near the mouth of the Miami River is a very healthful location, but not more so than some other portions of the State.

I think there is regular transportation from Miami to Key West, and from there north.

Pineapples, cocoanuts, guavas, and other tropical fruits can be raised in that part of the State with good profit. I think canning guavas and other fruits could be made very profitable, from Merrett's Island, on Indian River, south; or on the southwest coast of the State.

I can not advise a person where to locate and carry on other kinds of business in connection with an apiary, unless I know what that business is to be. Generally speaking, the north third of the State is considered a farming country; the middle third, the "Orange Belt;" and south of it, tropical fruits and truck-growing are getting to be the leading industry.

Life and property are as safe here as elsewhere, except for the hogs that run loose, and often break through fences, and destroy crops. We hope soon to have laws compelling their owners to fence them in.

The prices obtained for our honey are the same as those received for white clover, as most of it is shipped to the Northern markets, and is of as good quality.

Write to Hon. C. Drew, agent for the Bureau of Immigration, Jacksonville, Fla., for information as to transportation routes. Send him six cents for pamphlet issued by the Bureau.

Prices of orange-groves have a large range, eight hundred dollars being about the lowest.

New Smyrna, Fla., Jan. 12, 1885. W. S. HART.

BOOMHOWER'S APIARY.

THE HOME AND APIARY OF ONE OF OUR A B C SCHOLARS OF EIGHT YEARS' EXPERIENCE.

WE take pleasure in presenting to you in the accompanying picture a glimpse of a bee-keeper's home, and the arrangement of his bee-hives.

As friend Boomhower has sent us no explanation, we shall have to pick it out ourselves, for what I see. The very large hive where friend B. stands at work, we should think must be a chaff tenement hive. The engravers, not understanding bees, have probably omitted several details that a bee-keeper would have got in had he done

he receives pay accordingly. He is the architect of his own fortune.

I suppose the view was taken before the children got home from school, so you see none of these little prattlers about, and none near friend B.'s elbow, saying, "Pa, pa, may I have this?" etc. Did you ever think how much a man can accomplish by working steadily day after day, week after week, and year after year? If bee culture does not occupy all his time, or if he decides not to invest too much in bees in the start, he can at the same time have his garden, raise small fruits and berries, and have a great many other revenues besides that from his bee-hives. It is true, he has to battle for

FRIEND BOOMHOWER'S APIARY, GALLUPVILLE, N. Y.

the work. The small hives are evidently for queen-rearing. Some sort of instrument stands near the trees, which we hope friend B. will explain in some future letter. Very likely the picture was taken some June afternoon. Mrs. B. has finished her work, dinner things are washed and put away, and while she sits at the window with her magazine she looks out occasionally to where her husband is at work. Is not a bee-keeper's life in many respects a pleasant one? He is his own employer, and has only himself and his Creator to please. The blue expanse above is the roof of his workshop, the free air of heaven is all round about him, he is near his home—in fact, in his own doorway all the long hours of the day. If he works from early dawn until late at night,

success, and who does not anywhere? In all these things there is a sort of survival of the fittest going on; but a really industrious man, who plans his work and exhibits judgment and wisdom in the bestowal of his energies, rarely fails to gain at least the comforts of life. And then, dear friends, where he can make a living on his own premises he has one very great advantage over those who work for daily wages. No strikes, no shutting down of factories affect him—at least, not directly. If he keeps informed in regard to the rural industries of the day, he usually has plenty to do; and if times are dull, and the income is necessarily small, he must cut down expenses, and cut off luxuries. To tell the truth, I believe that thousands of people are happier while

cutting down expenses, and cutting off luxuries, than they are, as a rule, where they have money so plentiful that they can purchase almost every thing they think they need. Friend B. sent with the photograph the following brief letter:

I send you a photograph of my home apiary and queen-yard. I should be pleased to see an engraving of it in GLEANINGS. Eight years ago, when I first became acquainted with your journal, I never thought that I should have an apiary that would be shown in GLEANINGS; and if you will have an engraving made of the photograph, I will send you \$5.00 per year until the engraving is paid for.

Gallupville, N. Y.

F. BOOMHOWER.

I have allowed the concluding clause to go in print, because some of the friends have felt hurt when I told them I could not afford the expense of engraving their many apiaries, and that the few we did engrave must show such marked advantages that it would be profitable to our readers. The above picture cost an even \$40.00 for the woodcut alone, and we will have as many engraved as you choose, if you will pay the expense of the engraving, as friend B. has done. The picture is to be your property after it has once appeared in GLEANINGS.

HEDDON'S LANGSTROTH HIVE.

AND SOMETHING ABOUT HEDDON'S SYSTEM OF MANAGEMENT.

REGARDING the hive I have just sent you, I will give you most of the points that I claim as original preferences, devices, and inventions of my own. I prefer no wider space than 11½ inches, for 8 frames. I prefer to have the ends of the brood-chamber thicker than the sides that are nailed to them, and both ends and sides thicker than the bottom that is nailed to them. I prefer a cover never more than ¾. I much prefer to have the capacity of my hives not to contain over 8 L. frames. I would use no other than a light readily movable hive.

I find no gain in having a slanting alighting-board for the bees. I prefer thick end-bars and top-bars for my frames. I prefer a V top-bar, where no wires and only foundation starters are used in the frames.

My inventions consist first, of the reversible bottom-stand, so constructed as to take the bottom-board cleat, and let under no bees in front, and give earth ventilation behind, and being perfectly simple and cheap.

Second, the manner of cleating the bottom-board, as combined with the stand. (In moving hives we never have to move the stands.)

Third, the sink skeleton honey-board, so constructed as to form a bee-space above and below its slats; its slats so arranged as to exactly break joints with the top-bars of the brood-frames, thus preventing the attachment of bits of comb, and at the same time giving most perfect freedom to the passage of the "heat and odor" of the hive, and consequently the workers.

This honey-board is most easily adjusted or removed; at the same time as perfectly allowing the same easy adjustment or removal of any surplus receptacle resting upon it. It has a strong tendency to keep the queen below it—so much so that

queen-excluding honey-boards are of no use to me in my system of comb-honey production. It is so constructed as to be at once adapted to hives not designed for it, and to leave the hive perfectly bee-spaced, should one not have enough of them, and have to use the hive without it, as I have had to do with a part of mine several seasons. I consider this honey-board almost an actual necessity between stories of combs, when running for extracted honey. I think it my greatest invention. I have never found an objection to it.

Next comes my surplus case, which just now seems to be much liked by all practitioners, and which I think the best arrangement yet in use, for the production of comb honey without separators. I think, however, that some who are now using them will be forced to add separators to them, or abandon them for some style of super that uses separators. Not all bee-keepers can succeed satisfactorily without separators.

I have thoroughly tested metal rabbets, both with and without metal corners, and I do not like either. I used 25 hives containing them, for four years. I made my first metal rabbets (one hive, no corners) in 1871, after the direction of Mr. R. C. Otis, who visited me with sample, and owned the Langstroth patent for this and other States.

I call this hive "Heddon's Langstroth hive," for it is an L. hive with my modifications, and it is much modified. I consider Mr. Langstroth's bee-space above the brood-frames, as his greatest invention. By the reading of the specifications of his patent, I infer that he does also.

I have no patent on any claim of my hive. It seems to me there is as much there to patent as in any other hive that has been patented since Mr. Langstroth's. I never thought of a patent till I found there were men contemptible enough to wait till I had invented, and still longer till I had introduced, and then advertise "Heddon's hive," cutting the price a little, and the quality, and quantity of trimmings a great deal, giving no more material for the money than I did, and no valuable principles at all, except as they thus gave what rightfully belonged to another.

Now, your course of paying a reward for meritorious inventions, either that you might manufacture or might be placed in the hands of your readers, I feel sure has benefited the growth of our science and the subscription list to GLEANINGS. It was a just and wise act.

I know now of a bee-keeper who is using fixtures and methods that I know of (and I can not guess how many that I do not know of), that the bee-keepers of the world would be glad of. I asked him to write for our bee-papers, and tell all of his best thoughts. His reply was, "They would benefit the unjust as well as the just; the undeserving as well as the deserving. They would be used in direct competition with me; and the way of the business world is to protect one's own interests." I should never desire a patent to prohibit any user from making for his own use; but after my recent experience I see the wisdom and justice of the exclusive-right system, as adopted by every civilized nation; and should I, in time to come, again invent anything I think worthy of protection, I shall seek such protection of rightful pay for labor expended. While I appreciate your exclamation on page 620, 1884, as well as the many many inquiries I have had, asking if I gave my honorary consent to make

and sell my labor, I have found out it is only harboring the ideas of the perfectionist to imagine that our profession is not like others, more or less filled with those who will do right only when forced to by the strong arm of the law.

I feel that the great part of our profession need no laws, patent or any other; but as long as we harbor within our ranks quite a number that do, I say patent when you think best, and give us the results of your many wakeful nights (when you were stealing from your lease of life); *patent it*, but give it to us; don't keep it under a bushel. We want it, and are willing and can afford to pay for it.

My style of reversible frame as inclosed in the hive is described in A. B. J. Comments and questions are now in order. JAMES HEDDON.

Downglac, Mich., January, 1885.

Below we give an engraving of the hive in question.

HEDDON'S LANGSTROTH HIVE.

E represents the cover, which is a plain piece of board $\frac{3}{4}$ inch thick, cleated across the ends. Very likely a board planed as thin as this, and only $12\frac{1}{2}$ or 13 inches wide, would not warp to make much trouble, if kept well painted. But we have had very much trouble from covers warping and twisting, when made 16 inches wide and $\frac{3}{4}$ inch thick for Simplicity hives. In fact, we never succeeded in getting any sort of a cover for Langstroth hives that would not, sooner or later, let bees get under the edges, until we adopted our well-known Simplicity cover and bottom-board.

The case of sections D is so well described at the end of this article that we need not go over it here. The above case has three division-boards, as will be noticed, giving room for 4 rows of sections, 7 sections in each row. As a width of sections 7 to the foot has been so many times mentioned, we presume this case is just 12 inches wide. It holds the same number of sections, it will be observed, as does our case, only they are narrower. The sample hive mentioned has not yet reached us, but I presume the bottoms of the sections are flush with the bottom edge of the case, except the sheet of metal that separates them.

G represents the skeleton, or sink honey-board, as friend H. calls it, which is the special feature of his system of management. I will have a good engraving made of this

honey-board for our next issue, nothing preventing.

Hive A is simply an ordinary Langstroth hive, omitting the sides of the portico, and using the ordinary triangular blocks to adjust the entrance. The arrangement of the bottom-board and stand will be given in our next.

As mentioned in another column, no one is expected to advertise Heddon's Langstroth hive unless he first makes arrangements with Mr. H. for so doing; and even after having made this arrangement we are all to sell them at his prices. These we extract from his circular, as below:

All who are acquainted with our hive, know that what we mean by a "hive in the flat" includes about twice as much as is usually sold under that term. There being two surplus stories, makes it really a three-story hive, as we sell it, either made up or in the flat.

One hive made up, complete, with 2 cases and 56 one-pound sections..... \$3.00
One hive complete, with two broad-frame supers and 48 one-pound sections..... 3.50
One hive, arranged for extracting..... 3.00

PRICE IN THE FLAT, FOR COMB OR EXTRACTED HONEY.

One hive, nailed together..... \$2.00
Two to five hives, all flat, each..... 1.50
Six to ten hives, each..... 1.40
Eleven to twenty-five hives, each..... 1.30
Twenty-six to fifty hives, each..... 1.25
Fifty-one to one hundred hives, each..... 1.20
Heddon's skeleton sink honey-boards, each..... .25
per doz..... 2.50
per 100..... 15.00

We think the above cheaper than most beekeepers can make them, as it requires experience and a special form to make these honey-boards as they should be made. We sell them only made up complete. With these boards, no queen excluders are of any use in the production of comb honey, and they are equally advantageous in the production of extracted honey.

On page 81 the question is raised, whether anybody has a right to make Heddon's style of case. If I am correct, friend H. does not claim that the case is his invention; and so far as I can see, it is substantially the case used by J. P. Moore, of Binghamton, N. Y., as far back as 1876. Below I give you some extracts which I have taken from page 72, April GLEANINGS for 1876:

Well, I see you don't want any advice about hives, so I suppose this will be paper thrown away; but if you will read it and consider, I am satisfied: for if you don't have the best rack in America, the responsibility won't rest with me. I know you won't adopt it, because you are like me and a great many other bee-keepers — you can't be told any thing till you have the experience and see the reality.

Inclosed is a description of our rack as we now make it:

J. P. MOORE'S RACK FOR BOXES AND SMALL FRAMES, LANGSTROTH SIZE.

Take stuff 7-16 inch thick, by 2 $\frac{1}{2}$ wide; cut 4 cross-pieces $15\frac{1}{2}$ inches long, and 2 side-pieces $21\frac{1}{4}$ inches long. Nail through the side-pieces into ends of cross-pieces; put 3 finishing sides into each end of every cross-piece, putting together so as to form 3 boxes or spaces, without top or bottom; each to be $6\frac{1}{2}$ inches wide by $15\frac{1}{2}$ long by 2 $\frac{1}{2}$ deep. Get Russia sheet iron, cut with a machine, 2 pieces for middle $\frac{3}{4}$ inch wide, and 2 for end-pieces $\frac{3}{4}$ inch wide; punch 5 holes in each, on a block of hard wood, with a square-end punch, so as to take a piece out; punch the $\frac{3}{4}$ -inch ones along the middle, the $\frac{3}{8}$ ones a little nearer one side, and nail these irons on the bottom edges of the cross-pieces of the rack, with $1\frac{1}{2}$ -inch finishing nails, letting the edges project $\frac{1}{4}$ inch into the spaces, to support the ends of boxes and small frames, when set down into the spaces. Use boxes and small frames $6\frac{1}{2}$ inches long in this rack, of such width as to leave $\frac{1}{8}$ inch shake.

J. P. MOORE.

Binghamton, N. Y., Feb. 22, 1876.

If the above describes what friend Hatch wants to make, of course there is nothing to prevent his making as many as he chooses, and selling at whatever price he thinks proper.

GAURA BIENNIS.

AN UNFAVORABLE REPORT.

MR. ROOT:—I see in recent numbers of GLEANINGS that *Gaura biennis* is still occupying your attention. As I have made it the subject of some investigation, perhaps my experience might be interesting.

In the fall of 1883 I found my bees bringing in great loads of honey, very early in the morning, although nearly all honey-gathering seemed to stop at about seven o'clock. Anxious to discover the source of this honey, I walked out along the river one morning before sunrise, and there, alongside of a patch of sweet clover I found a sight that reminded me at once of your experience with the spider plant. On tall, coarse-looking plants were numerous curious-looking flowers with long sprawling petals of a delicate pink color. The beauty of the flower, however, was completely eclipsed, to a bee-keeper's eye at least, by a large drop of nectar which hung in the midst of the long downward-turned stamens—a drop so large, in many cases, that one bee could not take it all.

As I looked upon the globules of nectar glittering in the rising sun, and found that when one drop was taken away another began to form immediately from the fluid which could be seen issuing from the nectaries of the flower, I thought I had made a great discovery. Visions of barrels and tons of honey floated through my mind, and I longed to have all the roadsides and waste places filled with this wonderful honey-plant, with bees enough to gather all of the honey.

I broke off a branch of the plant, and, going home, interviewed the botany before the breakfast-table had any charm for me. After settling in my mind that it was the *gaura* I began collecting information in regard to it, and found that it was apparently a new plant in the locality; for while it was found abundantly along the roadsides and on the sandy river-bottoms, no one remembered having seen it before that season. In the meantime, the hives were filling up slowly with a very dark, thin, and unpalatable honey. Under the circumstances I concluded to learn more about the plant before reporting on it, and an article written on the subject was consigned to the flames.

Last season, *Gaura biennis* was conspicuous by its absence, as only a very few scattering plants were to be found. Again I concluded to wait; and but for your remarks in GLEANINGS of Jan. 15 this would not have been written. I will say, in defense of *gaura*, though, that some of the honey which I have yet, has improved very much since it was gathered.

J. A. GREEN, 118—118.

Dayton, Ill., Jan. 22, 1885.

Friend GREEN, I am sure we are very much obliged indeed, even though you have tumbled our air castle all into fragments. Please send me a sample of the honey in the little vial we mail you in a block. Now, I wonder if the character of the honey is not largely affected by the soil. It is so with melons, and also with sugar-cane, especially early amber. Is it not possible that the rank soil along the river-bottoms had something to do with the flavor of the nectar? Another thing, I should not be surprised if it transpire that the spider plant, Simpson plant, *gaura*, and others, would not bear honey of

any account, unless they have a strong deep soil. The *gaura* that was in our garden last season grew where sods had been piled for a foot or more. Some poor clay was mixed with it, however, and thrown over the top. The nectar looked so transparent and beautiful, it seemed to me as though it must produce nice honey. Are you quite sure your dark poor honey came from the *gaura*? From your statement it would seem quite probable, but yet we sometimes get sadly misled in these things. I do not wonder that your breakfast had no charms while you were hunting the botany, friend G. Can any other brother give us a hint? Another fact: Experience seems to show that many of our plants bear honey only occasionally; that is, it is only once in several years that we have a season just right for that particular plant. Honey reports have verified this repeatedly. Some plant hitherto unknown is found everywhere in the greatest profusion, dripping with honey, and next year it has all disappeared, and so on for several years after. This fact makes the raising of plants for honey a very uncertain speculation.

A VALUABLE HINT FROM ONE OF OUR CANADIAN BEE-MEN.

"Honey on a Stick, at 5 cts. a Lick."

A SHARP RUSE TO GET RID OF CROOKED AND IRREGULAR SECTIONS.

I SENT you a telegram one Saturday evening, ordering 25 queens, and on the next Wednesday morning I received them all, without a single dead bee. That is what I call business.

Our honey crop in this locality is hardly half that of last year. I have just finished feeding 7 barrels of granulated sugar to 157 stocks.

We exhibited over a ton of honey at our county show here last week, and took in over \$80.00 in cash for honey sales, chiefly in quantities of a pound or less. My son cut the pound sections into four triangular pieces by cutting diagonally from corner to corner, and then breaking the section into four pieces, to each of which a triangular chunk of honey was attached, and the furore he got up in the crowd for treating each other to "honey on a stick" was a new feature in the show. He also had extracted honey in 5, 10, and 20c. packages, but the comb honey cut in the presence of the crowd was so toothsome that it became "all the go." They are saying now that the bank-bills taken in by the treasurer were stuck together with honey, and that the demand for dry goods has increased, several dresses being injured by honey in the crowd. If any one has any crooked or bulged sections which he can not crate, this is just the way to turn them into cash at twenty cents each, because they will do to cut up, just as well as the best grade. S. CORNELL.

Lindsay, Ont., Oct. 9, 1884.

Well, friend C., your son is a genius indeed, if he got that up himself. The only drawback I see is, that in cutting the honey a good deal of "juice" would run out; but perhaps he let this drip into some of those cans, and then he would be that much ahead. Just about lunch time I should think it might be quite an idea. I have myself been studying about comb honey for a lunch, for a good many years, but I think your idea is ahead.

POULTRY FOR BOYS.

A SHORT TALK ON THE HEN BUSINESS, FOR THE BENEFIT OF THE JUVENILES.

ONE of the pictures that are in our tencent poultry-book pleases me so much that I have borrowed the electrotype to show it to you here in GLEANINGS.

You see, boys, this house is to be put in one corner of the dooryard. I suppose the northwest corner would be the best place, if you have such a one available. This will allow the sun to shine in at that window on the south side, and the entrance for the hens is also on the south side, while the door is on the east side, where we have fewest cold storms and winds; and when you open the door to go in, there is not so much danger of letting a cold blast strike some old biddy with a setting of eggs. I think if I were you I would have a tight board fence on the west side, unless there is a barn or some sort

A BOY'S POULTRY-HOUSE.

of building to keep the wind off. Or if it should be handy for you to put it where the manure from the horse-stables can be banked up on the north and west sides, all the better. If the pile get so high in January and February that a part of it goes on the roof, still better. On the north side of the building place the roosts, and under them have a long box, to be kept always full of ashes. Bury some corn in this box of ashes for a day or two, and the hens will get such a habit of scratching in it that they will scrape the manure all over every day, so that it will be so inoffensive you can handle it without finding it in any way disagreeable. Once in a while you can shovel it out and put it in a barrel, and then put in some fresh ashes. Underneath this ash-box you can have your nests. The best thing that I know of for a hen's-nest is a flour-barrel with a hole cut in one side, big enough for a hen to crawl in. Set this barrel under the ash-box behind the door, and your old biddies won't feel as though their preference for privileged privacy were violated every time somebody opens the door. When the weather is warm, the door can be left open all the while. The size of this house should be 4 x 6 feet, and 6 feet high on the side where the door is. In the summer time, take out the window and slide it under a couple of cleats put up under the roof, where none of the

glass will get broken before it is wanted again next winter. Some coarse wire netting may be put over the window when it is taken out in the summer time. Any boy, twelve or fourteen years of age, should be able to build this house well himself. The sash he can buy, or get one from some old building.

Now a word in regard to the contents of that ash-box under the roost. One spring when my father was planting corn I told him I would plant half of his field myself, if he would give me all the corn my half produced more than his half, and I told him that he might have his choice of the two halves. He took me up right on the spot. Do you ask how I knew my half would beat his? Why, I knew it would because I was going to put a handful of ashes and poultry manure under every hill on my side, and I knew he wouldn't fuss to do that with his side. Well, my side did beat; and although

I can not remember how much more corn I got than he did, I remember there was enough, or nearly enough, to keep my chickens through the winter; and we can set it down, that if the manure is properly applied, in the way I have suggested, it will pay for the food the fowls eat, and you will have your eggs and chickens clear gain, or pay for your labor.

May be somebody will say such articles as this have no business in a bee-paper; to which I reply, that if you look in GLEANINGS you will see that "peace on earth, good will toward men," comes before a word is said about bee-keeping. I am getting the children interested in rural pursuits, which goes a very great way toward the fulfillment of the above little text.

MICHIGAN STATE CONVENTION.

WHAT I SAW AND LEARNED.—NO. 3.

I MENTIONED in my last, that the sense of the convention seemed to be that wide frames for holding separators were to be discarded. They are to be used only in a crate placed over the honey-board, as described last month. The favorite way of supporting the sections seems to be one used a good many years ago, and illustrated in GLEANINGS as long ago as 1876, January issue. The crate is what might be called a half-story, placed over the honey-board. The sections are put in the same way as they are in our crate, illustrated on page 19 of our price list, only that a division-board made of thin lumber separates each row of sections. The sections are held from falling through by means of a strip of tin or Russia iron nailed to the lower edge of this division-board. This leaves the bottom-bars of sections just $\frac{1}{2}$ of an inch from the honey-board, and there is nothing to prevent the bees from walking over the outside of the section; that is, the bottom-piece of the section. I have always objected to this, and I think yet that I do not want a bee to ever look at, much less

step on any part of a section box; and to protect the sections I would have them rest on a thin strip of wood, the way our crates are all made. Prof. Cook also said that the bees should not be allowed access to the outside of the sections. The crate he is using, however, does permit the bees to get to them just the way I have described. President Hutchinson and others declare, however, that, with the honey-board, the bees did not attach bits of wax or propolis to the sections. While at the college apiary with Prof. Cook and the other friends, I noticed that his crates and honey-boards were covered with bits of comb, and the same sort of varnish that our bees spread over every thing here. It is quite likely that the damage they do in some localities is trifling; but I should want, if possible, to avoid the necessity of being ever obliged to scrape and sandpaper sections filled with honey, in order to have them look fit to take to market. With the arrangement mentioned we can have sections of different widths in the same crate, if we choose, by dispensing with separators. It is true, a separator could be used for each section; but the expense for such an arrangement is so great I believe it is mostly abandoned.

REMOVING SINGLE SECTIONS, AS SOON AS SEALED OVER.

Another point comes in here, however, which was discussed considerably. If we dispense with separators, we can not look over our hives, and pick out the central sections, or a section here and there, as soon as it is finished. The difficulty is, that when you put an empty section in between two partly filled, the bees will bulge the partly filled ones over into the empty one, if not prevented by separators. If I am correct, those who advocate no separators leave their crates on the hive till the sections are all completed, or nearly so. By tiering up this can be got along with very well, except that a section of honey looks nicer the day it is finished than it ever will again. Every day the bees travel over the white-capped surface, it is more or less soiled; and when that beautiful white appearance, so much admired in fresh comb honey, is gone, with most people the price must deteriorate. It is like the bloom on grapes—you can not well restore it.

In the face of these objections, however, the president and others produced comb honey that took the first premium at the different fairs, and used no separators. One member present, whose name I have forgotten, said that he made sections of honey answer the same purpose as separators, by having one with at least one side capped over on each side of every empty section; that is, when he takes out a filled one, and puts an empty one in its place, he transposes them so as to get them as above. President Hutchinson recommends that sections be not more than 14 inches in width, and that they be filled full of fdn., and not to give the bees too much room at once, when you wish to dispense with separators. Thinner combs are sealed over sooner than thicker ones, as less time is needed to evaporate the honey to the proper consistency.

POLLEN AND DYSENTERY.

Considerable time was spent on the above subject, although the matter has been much talked about for more than ten years. When GLEANINGS first started, or even before that time, I gave reports in regard to experiments with bees wintered on combs containing absolutely no pollen, and the result then given was, that when wintered thus they were generally if not invariably free from some of the worst features of the bee-disease generally termed dysentery.

AN IMPROVEMENT SUGGESTED ON OUR BEE-HIVE TENT.

One of the friends mentioned that a suitable-sized hole in the top of the tent would allow the bees that collect inside to get out at their pleasure, but robbers would never find their way in. I am inclined to think this would generally prove true, and we shall make some experiments in regard to it as soon as bees fly again. One friend asked what would become of young bees that escape in this way, were a tent spread over some cases of honey, for instance, the honey being just removed from the hives. The general impression seemed to be they would be lost. But I suggested calling them together by a spare queen that might not be of any particular use otherwise.

ARE TWO ENTRANCES ADVISABLE?

The general impression seemed to be they were not, and reasons were given why they were not advisable.

WHEN TO PUT ON THE SECTIONS OVER A COLONY.

Dr. Whiting advised waiting until white fins of comb were beginning to show on top of the frames over the cluster.

TIERING UP CRATES OF SECTIONS.

When a crate of sections is partly finished it is quite customary to raise it up and put the case of filled empty sections right under it. Where the colony is strong, the bees often fill the two cases, and sometimes even three. Well, by the usual process of tiering up, the bees are constantly walking over the tops of the sections, between the two crates of sections, and they thus have an opportunity to propolize the tops of the new set, as well as the bottoms of the old one. Many of the friends thought this not objectionable; but it seems to me it would be in our locality. With wide frames there is no space at all for the bees to pass between the upper and lower tier of sections.

DOES THE CRATE OF SECTIONS NEED AN OUTER COVERING OR CAP?

Secretary Cutting thinks it does, and my experiments have satisfied me that in our locality we want an outer covering. President Hutchinson thinks, however, that many times the bees are too hot within, and that the outer case would be like an overcoat in the summer time. Mr. J. H. Robertson, who has used the Heddon case largely, also agrees with the president, that no outer covering is needed. The point is, do we or do we not want the sun during hot days in summer, and the wind during cool nights or days which also occur sometimes in summer,

to strike directly on the crate that holds our sections? Some years ago I decided that we want protection, because without it I find the bees would not work well on the outside sections; but after a protection in the shape of an outer case was furnished them, they went right into the outside sections and filled them almost as quickly as the inside ones. This matter needs a careful looking-into.

MAKING FOUNDATION STICK TO SECTIONS.

When using the Parker fastener, or other similar devices, several of the friends have had trouble from the fdn. dropping off; but the general conclusion seemed to be that it was because the sections were not dried in the sun, or near a stove, before putting in the fdn.

PUBLISHING STATEMENTS IN THE BEE-JOURNALS, THAT SEEM TO HAVE THE STAMP OF MISTAKE OR FALLACY ON THE FACE OF THEM.

Prof. Cook gave us an excellent essay, where he good-naturedly rebuked quite a number of the brethren. He thinks the papers which have been published in regard to the conversion of worker-eggs into drone-eggs, by the bees; also getting queens that lay worker-eggs, without ever having met a drone, etc., should never have appeared in print. I thought so for a good while, and kept the letter on the latter subject for six months before I published it. Now, I am not yet satisfied that this thing is a mistake or a fallacy; but even if it is, it seems to me it has had the effect of bringing out a good many facts. I have sometimes thought that it is a good plan to make the brethren defend their positions, and the most that we accomplish in bee culture, or any thing else, is by a multitude of testimonies and experiences. It is, however, quite true that we may carry things too great a length, and I thank friend Cook for his timely caution.

CARNIOLAN BEES.

A letter was read from A. J. King, of the *Bee-Keepers' Magazine*, and from Mr. Shuck, of Iowa, extolling the above bees quite highly.

Concluded in our next.

MY REPORT FOR 1884.

SHALL WE THROW AWAY OUR ODD-SIZED HIVES, AND GET NEW ONES ALL UNIFORM, ETC.?

THANK you for publishing my article in Oct. GLEANINGS, even if you did take the head off the thing. You are quite a hand to decapitate and curtail; and although I do not always quite like it, it may be that my articles are often like a snake—better without a head; or like a hornet—better without a tail. In answer to your criticisms of my article (page 663, Oct. GLEANINGS), I would say: My idea is, that when one has the stock on hand of hives, honey-boxes, etc., it is better to utilize them, even at some inconvenience, than to throw them away. When one is buying, or making and building up in movable-comb hives, he should by all means have them all alike.

I have tried this diversity of frames a little; not much, but enough to become thoroughly disgusted with it. But when a stock is doing well in odd-sized frame or box hives it is better to leave them alone until for some reason it becomes necessary to manipulate them. Before you go to the expense of money, time, and waste, be sure that the gain will overbalance the loss. The cost in such cases generally exceeds the estimate.

I did not advise investing in bulk honey-boxes. I said, use what you have rather than throw them away. It might, indeed, be well to cut the honey out of newly filled frames when customers bring vessels to your house to be filled. But when the producer must furnish them, 5-lb. boxes are themselves such splendid vessels that I actually bought some this year, and expect to make them pay well.

ROOT'S PRICE LISTS

Are a great boon and a great temptation to a fellow. It contains much valuable information for the novice, and catalogues almost every thing an apiarist can want. But, just what to get is the problem. There are so many little notions it would be so nice to have, and at low cost too; but, cheap as they are, if one attempts to get them all he may suddenly find himself minus a certain article *more* essential than all. I have had to revise an order several times after counting up the bill. Not every *handy* article is a *necessary* one.

MY REPORT FOR 1884.

Bees did very little in this locality this year. Nobody obtained much honey, and some got none. My bees came through winter mainly in good condition. Gooseberries bloomed as usual about April 25th, and for about a week furnished some honey. Peaches did not bloom, and neither apple blossoms nor dandelions yielded much. White-clover heads make their appearance about May 20th, but it is two or three weeks later before bees begin to accomplish much. My bees were in fair condition to reap this harvest, the Italians and hybrids much in advance of the blacks. The first swarm issued June 5th, and one colony went to work in sections at the same time. In the next month they gathered their honey and did their swarming—more of the latter than of the former. The hybrids did the most of both. This swarming would not vex me so very much if they would not *hang* and “talk” about it so long before they get at it. After filling every thing below they would *hang* out in front, crawl half way up the sections, and *hang*; or some would build a little comb, then concluding, I suppose, they were not going to wear out their lives storing honey to leave with the youngsters at home, would stop work and hang to what they had built until they got ready to swarm. The only thing I could do was to swarm them myself; and that, it was not always expedient to do. Early in July, drought set in. Many of my new swarms were just getting to work, or ready to work. White clover bloomed in profusion during July. Subsequently we had a large crop of heart's-ease, and I never saw more Spanish-needle blossoms in my life. Yet after July 4th my bees did not store 10 lbs. of comb honey. This in spite of the fact that we had good weather with some refreshing rains in August and September. Now, what was the reason? I never saw so many grasshoppers, crickets, etc., in my life. When crossing a meadow there would be a perpetual cloud of these skippers in front of me. Is it possible that these bugs caused to any extent

this scarcity of honey? I was not bothered with honey-dew.

The aggregate result of the year's work is an increase from 39 to 63 stands, which I reduced to 50; about 10 lbs. of comb honey per stand, spring count, and about 180 lbs. extracted honey. As a rule I have obtained a little better price this year than last. Sixteen cents per pound is the price I got in Springfield. A very poor season altogether.

HOW I TELL WHEN SECTIONS ARE FILLED.

Simply look and see. I use the L. hive. The cap rests on cleats nailed on to the sides and ends of the brood-chamber. I fix the rack, cases, or frames, as the case may be, on top of the brood-chamber, and put glass on one or both sides of the section arrangement. I have nothing to do then but lift off the cap and look. No surplus arrangement is satisfactory to me without this feature. You can tell when sections are about full, by the editor's method (page 664), but not when sealed over. I write this for the benefit of W. Connally.

WHAT TO DO WITH UNFINISHED SECTIONS.

I have tried to get sections filled by feeding honey, but have not yet been able to make it pay. I can make the unfinished sections pay for themselves much better. There is money in them, if we do have to wait some time before we realize it. They are the cheapest and handiest bee-feeders I have yet seen. We have only to set the box on the alighting-board, or in the upper story, and the thing is done. And these empty boxes of comb are splendid to tempt bees up into surplus boxes early in the season. I am willing to have a thousand of them to hold over till spring.

Is chaff in cushions, which has become moldy, as good an absorbent of moisture, and non-conductor of heat, as that which is fresh? Should chaff in such cushions be renewed every year?

A grocer in Springfield tells me that California honey always brings a higher price in the market than any other. Is that so? GEO. F. ROBBINS.

Mechanicsburg, Illinois.

I suppose, friend R., this matter of throwing away our old hives depends considerably on what we are going to do with bees. If one is going to rear queens, and work for extracted honey, I would transfer my bees from the old hives at once, as soon as the weather was suitable; but if you were going to work for comb honey, you can, without very much expense, arrange almost any hive so as to take one of your regular cases, and then practice tiering up.—I know our price list is voluminous, and I have several times not only threatened but attempted to cut it down by the omission of some article not much called for; but almost invariably there comes a wailing note from some brother who looked there for just that thing or that arrangement above all others, and eventually I decided to put it back in the list again, as the lesser of two evils. Another thing, when I take something out of the price list not very much used, somebody keeps inventing it, and writing us letters with diagrams and long explanations. Now, you see by keeping the price list thus voluminous it prevents the friends from wasting time on something that has already been long in the market. In this way it makes a sort of cyclopedia, as it were, of devices and implements that have from time

to time been found useful in the care of bees. Since I have been interested in poultry I have looked in vain for a complete list of the implements used by poultry-breeders. Each one seems to go on his own hook, knowing nothing about what handy fixings his brothers may have. Another thing, no one makes it a business of making by nice machinery, at a small price, things that are now made laboriously at home. I have looked the poultry-books and poultry-papers over to find a convenient hen's-nest, and can not find any sort of one advertised. Now, some man with a factory might get up a movable nest having all needful good qualities, and, in fact, he might spend a year or two investigating all the nests in use, and he would then be better prepared than any single individual to make what is wanted; and with proper machinery he could furnish them at one-fourth of what it will cost an average day laborer to make his own. Now, if I am behind the times in this matter I hope some brother will straighten me out. A very cheap and simple nest could be made for a man of small means, and an elaborate, fancy one for those having fine expensive residences.—Your ideas are good on unfinished sections, friend R.; but is not nice white honey, clover and linden, for instance, rather expensive feed compared with the present price of sugar?—I would not have moldy chaff cushions at all. If they get damp, lay them on top of the hive till they get thoroughly dried out.—California honey will often bring a higher price than clover and linden, when first introduced; that is, where it is a novelty; but after a while I think the preference will be given to a nice article of clover honey, although much would depend, probably, on the quality of the California honey.

FIXING A SMOKER SO IT WILL HANG ON THE EDGE OF THE HIVE.

A SUGGESTED IMPROVEMENT BY FRIEND EAST-
TERDAY.

I THINK I have made an improvement in your Clark's smoker, which very much increases its usefulness. This improvement consists in so arranging it that it can hang on the upper edge of the hive, with its nozzle pointing toward the top of the frames. I have used one of a different kind for several years, which could be used in this way, and I found it to be of great advantage; especially was this so when handling cross bees, as I could drive them back at the first sign of danger by simply touching the bellows, without moving the smoker; whereas if I had been compelled to pick the smoker off the ground, the bees would have "got there" first.

This is the way I fix the Clark smoker: I rivet a small catch, or hook, to the lower side of the nozzle, close to the end. Then I take a piece of stout wire, about the size used for bucket-bails, 10½ inches long; 4 inches from each end I bend it at right angles, somewhat in the shape of the letter 'C'; then 2 inches from the ends bend again in such a manner that when the ends are fastened to the edges of one of the bellows-boards the loop will stand down at nearly right angles to the bottom of the bellows. This loop is to bear against the side of the hive, while the

hook catches over the top of the side (or end) board of the hive. The wire is fastened to the edges of the upper board of the bellows, with wire staples, or it can be fastened on top of the board in the same manner. By fastening it to the upper board, the smoker will remain stationary while the bellows is being worked.

It would make a better job, not to bend the wire the last time, but let the ends extend up past the end of the bellows, and fasten them to the sides of the cone; but they would have to be riveted on, which would be more difficult to do.

Nokomis, Ills., Jan., 1885. E. S. EASTERDAY.

Doubtless many would like the arrangement, friend E.; but I usually lay the smoker across the corner of the hive in such a way that it rests on the bellows, in the manner it appears in the price list. By simply touching the bellows, and pressing down a little, a puff of smoke will immediately be sent across the frames. There is one objection to this, however, for we may puff sparks among the bees unless the smoker is first shaken a little. The sparks and ashes should be blown out before the blast is turned toward the bee-hive.

CARP AND CARP-PONDS.

SEVERAL QUESTIONS ANSWERED, IN REGARD TO THE INDUSTRY.

SINCE the appearance of my article on the construction of carp-ponds, in GLEANINGS of Dec. 15, 1884, I have received several inquiries relative to this subject and carp culture in general. As I stated in my article, "My knowledge of the subject is based upon my experience in constructing my pond, and upon investigation, etc." Believe me, my experience goes but little further than in the construction of my pond, which was done last fall. It was not my intention to mislead any into the belief that I had an extended experience.

The subject is one in which I have been deeply interested for some time. I might lay claim to more experience than simply that derived from the construction of a pond, as my father-in-law has been engaged in carp culture for several years (since 1881), and is an enthusiast on the subject. Having paid frequent visits to his ponds I have had opportunity of learning something of the business. However, some questions have been propounded to me by my correspondents that I do not feel qualified to answer, much as I desire to assist those thinking of engaging in carp culture. This industry is comparatively new in this country, and there is much concerning it that is yet to be learned. Doubtless many things now considered as facts will be proven to be erroneous. With these points in view I feel that I ought to be careful that I do not so write as to mislead. That which I do not feel I know to be a certainty, I prefer to express merely as an opinion, based upon the best information on the subject at hand.

And now, Mr. Editor, with your consent I will introduce some of the questions that have been propounded to me, with the best answers I can give. I hope that any of your readers who may hold different opinions from myself will be free in expressing them.

"Can carp-ponds be successfully supplied with water drawn from a well by a wind-mill?"

I have never heard of such a case; though, with a well affording a large supply it might be successfully done.

"Will 'hard water' answer?"

Rather think there would be no objection to hard water. Very few springs afford "soft water."

"Do you think it will pay to raise carp for sale for food?"

I do. After you get your ponds, and get them stocked, there is but little after-expense. A neighbor remarked, a few days ago, that he believed there was nothing one could go at in which there was more money to be made. The question of over-production is the only one, I think, that can interfere with the business; and when we consider how few, comparatively, have locations suitable for carp-ponds, this objection seems to be removed.

"What varieties of carp are best?"

This is an open question. I have been told that only full-scale carp should be bred. Again, Milton P. Pierce, secretary of the "American Carp-Cultural Association," says, "All full-scale carp in this country are impure, inferior, and not worth breeding." The same authority mentions the parti-scale type of carp as being the best now obtainable.

"Have you 'carp for sale'?"

No.

"At what price do carp sell?"

I quote prices adopted by the Carp Association, above mentioned, at its meeting of Sept. 17 and 18, 1884, which is as follows:—

Young parti-scale carp, this season's hatch,
 Yearlings, " \$8.00 per 50, and \$15.00 per 100
 Breeders, " " each, 30c
 " \$1.00

"How many carp will do well in your pond?" (size 30 x 120 ft.)

I expect to introduce 50 in the spring, but suspect they will be somewhat crowded when they attain a larger growth.

"Do fish have to be fed regularly?"

Having abundant room, they do not. They doubtless do better by feeding, and there are few who will neglect this duty, if it is only for the pleasure of seeing them eat, as well as getting them gentle. It is said they thrive on cooked potatoes, bread, kitchen slops, etc.

Every one who expects to follow breeding carp to any great extent should have more than one pond. The "small fry" become so numerous that the larger ones do not do so well.

I would call attention to the American Carp-Cultural Association, above mentioned. The office is No. 323 Walnut St., Philadelphia, Pa. The association issues a circular, setting forth its objects, which will, I presume, be mailed on application to the secretary, Mr. Milton P. Pierce, at the above address. JOHN E. EVES.

Mooresville, Ind., Jan. 12, 1885.

Thank you, friend E. I would suggest that the prices you give are considerably higher than are asked by the friends generally who have received carp from the Government. I hope the Carp-Cultural Association will soon have a text-book out at a moderate price. While GLEANINGS always expects to be able to notice new kindred industries as they come up, we shall have to remember that it is primarily a bee-journal; and doubtless many of the articles we are

publishing could either be abbreviated or omitted, had we a text-book giving the facts contained in them. I am now engaged in writing a series of articles on bee culture that we expect to publish in a pamphlet for our ten-cent Industrial Library, and my convictions are that we want a book on carp culture that will cost just about this sum. Many of us enjoy reading a brief treatise on these new things, say about such a book as ten cents ought to pay for, where we could not possibly find time to go over an elaborate treatise. Am I not right? The books we advertise on squashes, cabbages, mango-wurtzels, and onions, are sold in great numbers; and as one can go through a book in an evening or two, he generally reads it through when he takes it up; but only the specialist can afford to go through an elaborate treatise.

CARP CULTURE, AND THE CONSTRUCTION OF CARP-PONDS.

KEEPING CARP OVER WINTER IN A TANK IN THE CELLAR.

ABOUT 300 feet south of my house I have a fine spring which made a wet swampy place below it about 100 feet square. Three years ago last summer, which was an extremely dry season here, myself and hired man plowed and scooped, and hauled out with a wagon about two weeks, and made a pond that was nearly in a circle, 60 feet in diameter; and when filled (which was not until New Year's) there was from one to four feet of water in depth. I received and put in my pond, Dec. 29, 1881, 16 German carp, about three inches in length, sent me by the U. S. Fish Commissioner. The last of the next February we found 3 that had died and floated out to the edge. They were about the same size as when put in. We watched very anxiously and frequently through the spring and summer months for a glimpse of them; but only one did we get to see, and then only long enough to be sure it was a fish.

On the 30th of the following August we found 3 that had died and floated to the edge, that astonished the neighborhood. Two of them measured 14 inches in length, and weighed $2\frac{1}{4}$ lbs. apiece; the other was 15 inches long and 12 inches in circumference, and weighed $2\frac{1}{2}$ lbs. We spent half a day in hauling them around and exhibiting them. Several of the neighbors that saw them could not believe they were the same fish put in about 8 months before, and only 3 inches in length. The next day we found three more about the same size. I wrote to the U. S. Fish Commissioner, and told him how I had found my fish, and gave him a description of my pond and the water, also the growth the fish had made, and asked for all the information he could give me, and asked if he could furnish more fish, as I was not willing to give it up that way. I received a card from him, stating my order should be renewed, but nothing more.

On the 24th of November, 1882, I received 22, from one to three inches in length, which were immediately turned into the pond, and they did not make their appearance again until July, 1883, and were fully 12 inches long. After that time they would come up and get bread on the water whenever the

weather was pleasant, until late in the fall, but did not raise any small ones that season.

Last spring, about the middle of April, they made their appearance again. They had not made much growth since the fall before. We had many friends come to see them, and they got fed frequently. On the 27th of July, when our little fish first made their appearance, the old ones looked as if they would measure from 20 to 24 inches in length, and were about the shape of the white fish we get from the lakes. Since the small ones made their appearance we have seen the larger ones but a few times. The little ones were from one to three inches in length when first seen. They have been well treated. A great many come to see them, and they always had to have a few slices of bread, which made them show to the best advantage. My wife sometimes said I would need another baker. We sometimes fed at three different places at the same time, and there would be a space three or four feet square at each place where they were pushing and crowding each other to get the bread. They would eat bread from my hand when held in the water, and often nibble my fingers. Sometimes I would get my hand under one and throw it out on the bank. The largest size of the small ones is from 10 to 12 inches in length. I have not seen them since Dec. 1.

Since losing our fish I have read an account given by a man in Germany, stating that he had known heavy loss from a stroke of lightning; and knowing that we had a heavy storm a few days previous to finding ours, we have concluded that was what killed our fish.

About the first of last November I built another pond just below the first one, which is about 100 ft. wide by 150 long. I laid a five-inch pipe at the lowest point, and built the embankment over it so that I can let the water out when I wish. I also made a box 2 feet square over the upper end of pipe for a strainer, by setting four posts 2 feet apart and 2 feet high, and nailing strips, 1 by 3 inches, $\frac{1}{4}$ inch apart, around and over it. I also made what is called a collector, still above the strainer, in the form of an A, and attached them together. The wings were 16 ft. long and 15 inches high, 14 feet wide at upper end, and same height as sides, and I put a floor in it. The boards run crosswise under the sides, and project one foot on each side. I then filled dirt on them, up to within four or five inches of the top of sides, to hold it down. The bottom of the collector was just high enough so the water would all run out through the pipe. I intend to let the water out of my first pond early in the spring, and put my small fish in my new pond; and if I am successful the coming summer, I shall have a supply of both large and small ones by the end of the season.

I have a neighbor, $2\frac{1}{2}$ miles from me, who has four ponds. He received fish from Washington when I received my first lot. I have been there to see him draw the water from one of his ponds twice—the 22d of last March, and the 11th of last November. The pond covers about half an acre. Last March there were about 500 fish in it that would weigh from 2 to 3 lbs. each, and they estimated the small ones at 5000, from 2 to 8 inches in length. The same pond had about half as many in November. He sold a great many for stocking ponds. He also made a place in his cellar, 13 feet long, 10 feet wide, and 20 inches in depth, which he cemented, and has a pipe running from his pump to it, so he can supply them with fresh water whenever needed. He

informed me a few days ago, that he had about 300 in there of different sizes, mostly small ones, put in about the 1st of Dec., and they were doing finely.

I see that I have forgotten to state that I enlarged my first pond in the fall of 1882, until it measured 110 feet in diameter.

W. H. CARPENTER.

Springboro, Warren Co., O., Jan. 12, 1885.

Thanks, friend C., for the valuable information you give us in regard to this new industry. One of our friends has sent us a book by Milton P. Pierce, of Philadelphia, fully describing the plan of making the collector you mention, and also some excellent ideas in regard to the construction of the outlet. There are some good things in the book, but it is a very small pamphlet, and the price is \$1.00. It seems to me too bad that we can not have a nice little book on this new industry for about 25 cts., or possibly a little more. I think the Government should see to it that some text-book like the above be furnished at a moderate price to those who receive fish. The valuable letters given through GLEANINGS would make quite a valuable little book; and if somebody else does not get at it, I do not know but I shall have to undertake the task myself. Perhaps the book could be boiled down so as to come within the scope of our ten-cent Industrial Library.

ALLEY'S DRONE-TRAP.

A PROTEST AGAINST THAT UNFAVORABLE REPORT.

W. FRANCES, in GLEANINGS, JUNE, 1884, says: "I set the trap before a stand of bees. They could pass out and in when so minded; but, about one-third of them, after making a trial, became united and went to other stands, and in less than a minute got up a fight. After making three or four such trials, I laid aside the trap."

Now, friend Root, you say the above is "not very favorable." But, what are we to understand from what friend F. has said, that he attempted to do by using the drone-trap? Did he place it on the hive to prevent swarming, or to assist him in case a swarm issued? I can not make out wherein the trap was a failure, or even had any thing to do with the bees going into other hives. Certainly, it was a very unnatural and unusual proceeding. If the bees, on attempting to swarm, went into the air, and, missing their queen, attempted to return, why did not friend F. say so? Why didn't he tell us whether the queen went into the trap or not, and, in fact, give us more of the particulars? It seems to me that his young bees were out on a "sporting flight," and, his hives being too near together, and the weather somewhat cool, they might have got confused, hence the trouble and failure. If the trap was placed there to prevent swarming, it should have been removed when it was evident that they would return to the hive, so that they could pass in.

It strikes me, that when such a thing occurred several times, I should have removed the trap, as an experiment, to see whether the trouble was cured by it or not. Now, had friend F. wanted his bees to swarm, why did he not remove the trap while the bees were on the wing, and place it near the spot where the bees were hovering, or perhaps settling?

Had he done so, they would have settled upon it; that is, providing the queen was in it, and then he could have hived them at pleasure. If he did not care to have the bees swarm, why not, when he was there to witness the operation, remove the trap, and, when the bees had gone in, released the queen. As you suggested, his hives must have been very near together, or such an occurrence would not have taken place.

Directions for using the trap were published in the *American Bee Journal*, and I am quite sure that friend F. had not read them, or he would never have had occasion to make such a report. The 3d edition of my book is in preparation, and I will endeavor to give such directions for using the trap as will prevent other unfavorable reports of it.

I append the report of one man who read the *A. B. J.*, and you can see how he managed. It is evident that friend F. did not understand how to use it. The trap in this case worked just as I intended, with the exception of the bees going into other hives, which I am quite sure they will seldom do in such cases.

As to the unfavorable reports, I can say that all the best hives, and, in fact, every thing we have in the "bee line," have had unfavorable reports made of them. But when people are taught how to use them, favorable reports will be made in all cases.

H. ALLEY:—I had a colony that swarmed, and the trap did its work beautifully. I am highly delighted at being so successful at my first attempt. The bees went off for a short time; but when they found their queen was not with them, they returned, and covered the whole front of the hive. I removed the parent colony back, and placed a new hive filled with foundation on the old stand and let the bees go in, releasing the queen from the trap at the same time.

B. F. NEWCOMB.

100 Washington St., Chicago, Ill.

Wenham, Mass., Jan. 16, 1885.

H. ALLEY.

But, friend Alley, it seems to me the directions for using the trap should be sent with each one. It is always customary to furnish printed directions, free of charge, with the article itself, if there is any danger of not being able to use it properly. Even though the directions have been given a good many times in the journals, to make a sure thing of it a copy had better be pasted directly on the implement. Printed directions cost only a few cents per hundred, when we buy them by the thousand.

FROM 23 TO 52, AND 2000 LBS. OF HONEY.

A REPORT FROM THE HEDDON STRAIN OF BEES, AND SOME OTHER MATTERS.

I COMMENCED the season with 23 colonies, which have done exceedingly well, considering the season. The bees did well on white clover, but at no time was the flow of nectar rapid. Basswood was of short duration, not lasting over a week. This closed our honey season, as the fall blossoms were a failure. I kept 15 stands for honey, and the remainder for increase and raising queens. During the season the number of stands was increased to 52, and from them 2000 pounds of extracted and comb honey obtained.

My bees are Italians and hybrids, of James Heddon's and Oliver Foster's stock, with which I am well pleased. Those obtained of James Heddon are

a dark leather color, and are a very active, hardy bee, wintering well, as they seem to bear confinement in the cellar in winter better than others. Those received from Oliver Foster are lighter colored, one queen being a beautiful, bright golden color. Some of the workers have four distinct bands. In one hive of the Foster stock the drones were the most beautiful I ever saw. By crossing these two kinds I expect to make a great improvement, as each kind has marked qualities.

I winter my bees partly in the cellar and partly on their summer stands. Those on the summer stands are wintered something on the principle of the chaff-tenement hive. The difference is, that I use the Langstroth hive, placing two facing to the north and two to the south. Then I make an outside box to go over the four, with four inches of space between the hives and the packing-box, which is to be filled with chaff. The packing-box is made high enough to cover a two-story hive, the bees being wintered in the upper story. A slat honey-board is placed between the two stories, which gives the bees a chance to poke the dead bees down below. An entrance is made by boring a hole in the packing-box and the front of the hive, and connecting the two with a tin or wooden tube. The lid is made with a gable roof; and, as the material used need be of only half-inch stuff, and of a cheap grade, the cost does not exceed 20 cents a hive, which is a great saving, considering what a single hive will cost when chaff packed. This plan may not be new to many of the readers; but as I have not seen any thing like it described in the bee-journals it may be of interest to some.

In an experience of seven years in bee-keeping I have met with many difficulties; but by reading books and journals of apiculture, a great many of them have been overcome. W. S. DORMAN.

Mechanicsville, Iowa, Jan. 12, 1885.

HOW TO USE EMPTY COMBS.

HOW TO MANAGE SO AS TO HAVE THE HONEY GO INTO THE SECTION BOXES INSTEAD OF INTO THE BROOD-FRAMES.

IN last number of GLEANINGS I gave you, by way of explanation, some comments on friend Hutchinson's article found on page 803, for 1884, but for lack of space did not say all I desired to. The main point in that article which I wished to speak of was, what caused the apparent failure of Mr. Hutchinson in using empty combs in the brood-chamber, while working for comb honey with newly hived swarms. Friend H. says, "I abandoned hiving upon empty combs, as the bees would fill the combs with honey in a few days—fill them so full that the queen found but little room to lay, then they 'loafed' a long time before commencing work in the sections; and when they did finally begin it was in a slow, easy sort of way."

Now, inasmuch as I always, of late years, have new swarms on empty combs, and that with good results, it becomes evident that there must be a right and a wrong way to use empty combs, when working for comb honey with new swarms. As I have stated before, the queen going with a swarm is not in a condition for rapid egg-laying until the swarm has been hived long enough for the bees to get under full headway building comb; hence if a full hive of empty comb is given such a swarm, the

first thing the bees will do is to fill it with honey, no matter how few or how many sections are given, for the bees have room in this brood-chamber for all of their immediate wants. If we extract from these combs we do not materially help matters, except to give a little more room to the queen; for after extracting, the first instinct of the bees is to fill those empty cells again, instead of leaving an empty lot of comb in the brood-chamber, to go to work in the sections. Thus we get only a little extracted honey for our trouble, while two such extractings will effectually exclude all honey from the sections; while not to extract is nearly as bad, for after once filling the combs in the brood-chamber with sealed honey instead of brood, the bees are always loth to enter the sections, for the reason I first gave, which is, that they feel that all their wants are well supplied. Now the trouble was with friend H. in giving the bees too many combs. By so doing the bees found room to occupy all their forces; while if only one-half or one-third as many had been given, the bees not being able to cluster and work on these combs, would have immediately gone into the sections, and gone to work on them. Having thus at once started in the sections, the little honey stored in the few combs below will be carried to the sections as fast as the queen needs room for egg-laying, and the result with me is, that at the end of 15 days from the time of hiving, the sections are well filled with honey, and the combs below a solid mass of brood, except a little pollen and honey in the extreme upper corners of the frames. The object should be in all cases, whether you use combs, frames of foundation, or empty frames, to get the bees at work in the sections immediately upon being hived. I use six Gallup frames of comb (equal to 5 L. frames) for the very largest swarms, while others have but 4 or 5, according to the size of the swarm to be hived, and in this way I always secure good results. The greatest secret of getting comb honey is to get the sections just as near to the brood as possible; and any plan which allows of one or more inches of sealed honey between the brood and sections is certainly defective. By hiving swarms on empty frames with sections filled with foundation, friend H. placed his bees in the right position to comply with the above secret, while with the hive full of empty comb the condition was exactly the reverse.

One other thing: While it is necessary, almost, to furnish a full sheet of foundation for every section when a swarm is hived, as H. recommends, such foundation is often nearly as good as thrown away while working on my plan, for I have repeatedly had sections filled and completed which contained only a small starter of natural comb, as quick as those filled with foundation standing by their side, while an examination of these latter sections showed that said foundation had not been touched, except as the bees added their wax to it. Now, why is this? The reason is very simple. All new swarms of bees have been preparing, for a week previous to the time of issuing, for the construction of combs in their new homes, and for this reason we often see little bits of wax, from the size of a pinhead and upward, attached in many places to the limb of the tree they have clustered on, if they stay clustered for five minutes or more. This wax being secreted, must be used somewhere or wasted. In friend Hutchinson's case it is used in building comb down in the brood-chamber, while the bees

are drawing out the foundation in the sections; while in my case it is used in filling the sections with beautiful combs, as they have no need for it below. From the above it will be seen that the reason friend H. and myself did not agree regarding empty combs was, that we did not manage alike, and I suspect that the different modes of management is what causes the "bee-doctors" to so often disagree.

Brethren, let us use more charity one for the other, for the different mode of management will almost always explain all differences of opinion.

Borodino, N. Y.

G. M. DOOLITTLE.

Friend D., I want to add emphasis to your concluding sentence. Your above paper makes it very clear why bee-keepers may obtain such opposite results when only a little variation is made in the method of management. You run very close in one place to this new subject of reversible frames; and if I am correct you have not given an opinion in the matter as yet, and, if I am not mistaken, it will be just like you to say you don't want any reversible frames around, for the reason, perhaps, that you accomplish about the same results without them that others would obtain with them.—I want to take out one of your sentences, and call attention to it: "Any plan which allows of one or more inches of sealed honey between the brood and sections is certainly defective." That is the sentiment exactly. I should want the best way to obviate such a result.

INTERNATIONAL BEE-KEEPERS' CONVENTION

At the Exposition in New Orleans, Feb. 24, 25, and 26, 1885.

SOME SUGGESTIONS TO THE BEE-KEEPERS IN REGARD TO GETTING THERE.

IN my letter to you of December 25, I tried to make every thing plain; but there seems to be a misunderstanding regarding the sleeping-car and passage-tickets. For the benefit of your readers I would say, it requires a ticket for passage, independent of the sleeping-car arrangements, and the sleeping-car rates quoted you were for one way only, and it would cost you just double the amount for the round trip that it would for one way. The Sleeping-car Co. is separate from the railroad company, but they are each necessary to the other. The railroad fare, Cincinnati to New Orleans and return, good for 15 days, is \$18.00; from Cleveland to New Orleans and return, good for 20 days, is \$25.25, and the same from Medina; and the rates from all parts of the United States and Canada are in the same proportion, and it will save them all money to purchase their tickets to New Orleans and return of their nearest coupon-ticket agent. To prevent any mistakes regarding the route, say to the ticket agent you want to go via the Louisville & Nashville Railroad from Cincinnati or Louisville, according to the section of country they are starting from; and a good plan for each one is to read his ticket carefully, and see that one coupon reads Louisville & Nashville Railroad, from Cincinnati or from Louisville, to New Orleans. As Thursday, February 19, is a good time to leave Cincinnati, I would suggest that you set that day for all those

desiring to accompany you to New Orleans to leave their homes so as to reach Cincinnati Thursday, the 19th, and leave there at 8:55 P. M., and arrive in New Orleans Saturday morning; then you have plenty of time to get located, and be ready for the convention on the following Tuesday. For those going on the above date, and desiring sleeping-car accommodations, it will be necessary for them to send you their names not later than February 12th, so the necessary arrangements can be made with the Pullman Sleeping-car Co. HERMAN HOLMES,
Traveling Passenger Agent.

Medina, Ohio, Jan. 17, 1885.

MEETING OF BEE-KEEPERS AT THE EXPOSITION IN NEW ORLEANS.

Your idea in regard to wearing badges, I think a capital one. You may count me one on your list of those who expect to attend the exposition in Feb. Hope to meet you and other bee-friends. This is the first friendly letter I have ever written you, but expect to let you hear from me oftener in the future. I have about 150 stands of bees. My crop of honey was short last season.

Of course, if the plan of wearing badges is adopted I shall wear one. Good old GLEANINGS is a welcome visitor. J. M. FORREST.

Midway, Texas, Jan. 10, 1885.

A BADGE FOR BEE-KEEPERS.

I for one object to a badge. Could you not design a small (say life size) gold or rolled gold bee or queen, which could be attached to the cravat or coat-collar? I think this would not be too conspicuous, and no bee-keeper would object to wearing one. I will take one or two at once; and if you have any made, mail me one. What do you say?

Bayou Goula, La., Jan. 10, 1885. P. L. VIALLO.

The subject was agitated some time ago, friend V. A golden queen-bee would cost quite a little money, but perhaps good plated ones might be afforded at a tolerably fair price. The only objection that I know of is on the ground of expense, and a good many of the brethren are already indulging in more extravagances than they can well afford. I do not quite like the idea of wearing a badge in public, but yet there are so many reasons why bee-keepers should know and recognize each other at a glance that I have a kind of feeling that it is the thing to do. Friend Newman, of the *A. B. J.*, has for sale some very pretty badges; but perhaps it would be a good idea to have one especially for the exposition at New Orleans. Perhaps before this journal goes to press we may make arrangements in regard to it.

THE CONVENTION AT NEW ORLEANS.

I notice in GLEANINGS of Jan. 1, your suggestions in relation to attending the convention in New Orleans. I shall be very happy to be one of the number of bee-keepers to attend, as suggested by you. Will you be kind enough to inform me what arrangements, if any, have been made in relation to the matter? Does the \$130 named by Mr. Holmes, as the sum for which a car can be chartered from Cincinnati to New Orleans, mean for the round trip?

S. P. WEAVER.

Leipsic, Ohio, Jan. 14, 1885.

Mr. Holmes, in the paper at the head of this, answers your question, friend W.

BADGES FOR THE EXPOSITION.

Your suggestion, that all the bee-men wear badges, and meet in Cincinnati when they go to New Orleans, just suits me. I propose that you make the badges, and let us know in the next number what you can furnish them at. It will be much more pleasant when we go in the cars, looking for a seat, to sit down with a brother bee-keeper than a baker or a butcher.

JAS. P. SMITH.

Franconia, Minn., Jan. 12, 1885.

I agree with you, friend S. If it were not for looking too conspicuous, I should like the idea of having one's name on the badge. For instance, when we are looking about in a crowd, and a good many are talking, there probably would be hardly time to inquire of everybody who he was; but if by looking at his badge we could see something like this, "I am A. I. Root, of Medina, O., who are you?" wouldn't it help us to get acquainted? I for one find it extremely difficult to remember friends I have been introduced to and talked with, and once or twice I have found myself shaking hands with one I had shaken hands with but a short time before. I do not suppose it did any harm, but may be some of the brethren might think I was a little eccentric or queer, and I for one don't want to be thought queer. I want to make my life count just as much as it possibly can for the Master, and therefore I want my influence to weigh every ounce it possibly can be made to. If having my name and residence on my badge would help me to help somebody else, I am willing to do it, whether it makes people stare or not; but if it should have the effect of making me look queer and singular, and thereby lessening the weight of my influence, then I do not want to do it. May be somebody can help us right here. We shall be a band of brothers down there, gathered from far and wide, and we may ride miles side by side with somebody we wanted to see most, and not know it, unless some precaution be taken.

THE PIONEER APIARY OF BRITISH BURMAH.

MAKING THE BURMAH BEES ADOPT SIMPLICITY HIVES AND A B C MANAGEMENT.

FRIEND ROOT:—A B C has arrived, and so has another swarm of bees. The swarm I wrote of was driven off by ants. I got another swarm, and robbers drove them off. A B C arrived, and now we are prospering. I do not know that you will yet admit me to the A B C class, but I have almost got my lesson—in theory I mean—but have little of the practice as yet. If it takes as many swarms of bees to make an apiary as hills of corn to make a row, we have hardly an apiary yet; but when we have one I think we must call it the "Pioneer Apiary of Burmah," for I don't know that there ever was an apiary before in Burmah.

I have had my swarm nearly two months. I had a Simplicity hive, made by my Burman carpenter, as nearly like the pattern as I could get him to make it. He thought I was very particular, and I was obliged to undo his work several times before it was completed. In due time I got every thing ready, and "a few things more," as A B C directs,

opened the old box in which the bees were brought from the hills, and transferred. Half the bees left for the roof of the veranda, a lot clustered on the head of my Karen boy, and the rest were on the comb and in the hive. In short, we made the transfer in a bungling way; but as we had brood, the little folks concluded to stay with us, and the next day were at work.

As there is an abundance of pollen about, and very little honey, I fed them slowly with syrup; and as a result they are multiplying very rapidly. Saturday last I opened the hive and spaced the brood and gave them a new comb in the center of the brood-nest, and they seemed to be immensely tickled with it, and set about gathering pollen, etc., with new vigor. I measured the cells, and found just six and a half to the inch; so you see they are little fellows. Nellie thinks that these bees have read GLEANINGS and A B C, for they act in almost every thing just as A B C says they ought to. It is most laughable to see the young bees come in with their first loads. Altogether they have brought a very pleasant element of pleasure and recreation into our mission circle. The natives are greatly interested, and wonder that the bees are so gentle, and that we can make them mind. They are *very* gentle. I do not think they would have stung at all in transferring, if we had not used an old feather brush, to sweep them down from the roof into the hive. They didn't like that, and attacked it with great ferocity. Four shot by, and paid me their compliments.

I notice that these bees are most active after four o'clock P. M. Then they are very busy bringing in pollen. At noon not one is stirring. In the morning a few are flying. About 2 o'clock almost every day they fly out, to stretch themselves apparently. Whenever I lift the cloth over the frames they look up to see what is coming, but make no sign of coming out. They post no sentries, save just at evening, when a few come out and fan at the entrance, and make a show of fight to every bee that comes in. In a little while they return, and any strange bee could easily enter the hive. When we first got them they roamed the house over, alighting on our faces, and crawling over our persons. At first the timid took to the mosquito-curtains (I was far off at my office); but as it was soon apparent that they only wanted to get acquainted, they were not molested, and stung no one. So much for the "Pioneer Apiary of Burmah."

THE STING OF A SCORPION.

I see some one says in GLEANINGS that red onions are good for stings. The sting of a scorpion is the sting of hundreds of bees concentrated, and I have seen natives stung by a scorpion, writhe in pain on the ground, yet, in fifteen or twenty minutes, freed from pain by the application of the fresh surface of the small red onion. It is a specific with us, and the first and last resort. Ammonia, etc., will fail, but I have never known the onion to fail. I never tried it with bee-stings.

A. BRNKER.

Toungoo, British Burmah, Nov. 21, 1884.

Many thanks for your kind descriptive letter, friend B. I was especially interested in this matter of the sting of a scorpion. I have sometimes wondered whether this scorpion poison is any thing like a bee-sting. How does the scorpion introduce the poison? It is not a sting like a bee-sting, is it? In regard to onion juice, I should think likely it might "hit the spot" if any thing would. So you have yourself really been stung by a

scorpion, have you, friend B.?—I am glad to know that your little bees behave themselves in accordance with the rules laid down in the A B C book. Tell Nellie I think she must be right, and that the little bees have got hold of the ideas in the A B C and GLEANINGS, even if they have not really read them, only that they had these ideas before ever the A B C book did. You pay me a compliment, Nellie; don't you see it? God gave the bees this instinct, and the instinct away over in Burmah seems to be about the same as with the bees here; therefore when I devoted those weeks and months to studying the habits of these little friends, I mapped (unconsciously) just the way they would behave under special treatment over there. We should like to know how much honey you get.

COMPLICATIONS IN BUSINESS TRANSACTIONS.

HOW MUCH HONEY SHOULD NEIGHBOR S. GIVE FOR
II COLONIES OF BEES IN BOX HIVES?

A NEIGHBOR has eleven good swarms of bees in high box hives. He is sick of bees, and wants to know how much honey I will give him for them (the honey to come from next year's crop). As I use the Simplicity hive, I shall have to transfer them all, and work over the box hives into Simplicity hives. Now, how much honey can I give him per swarm? This is a fair honey section, but few bees kept here, all in box hives.

I am an A B C scholar, and practiced on three swarms last summer. I got 57 lbs. comb honey from a swarm put in June 12; 25 lbs. from each of two more put in June 26th and 28th, besides all are very heavy with honey for winter. I have them all in the cellar. JAY S. SEELY.

Sodus Point, Wayne Co., N. Y., Jan. 12, 1885.

Friend S., you will, if you take my advice, instead of saying *honey*, say *money*; and if you can possibly manage it, I would pay the cash down for the hives, and take them home. Trades and swaps like the above, or sometimes a great deal more complicated, have been the means of making more quarrels than almost any other one thing; whereas, had it been a simple purchase there would have been no room for misunderstanding and hard feelings. Almost every day I hear of some quarrels or jangles that come about by complicated business transactions, when it might just as well as not have been a simple purchase. Perhaps you have not got the money to pay. In that case, without knowing you or your neighbor, I should almost feel like saying, don't buy the bees until you have the means to pay cash down. If you want the bees very badly, you can rake and scrape up the money to pay for them in a few weeks, in all probability, before you will be ready to make any use of them. Probably you will get some honey from the bees next year, yet a good many bee-keepers carry eleven colonies or more through the whole season, without getting a pound of honey. I do not believe there is any need of so doing, in scarcely any locality, yet such things are reported, as you will see by Reports Discouraging. Now, if

you want to make the sale conditional, I would give your neighbor a note for the bees, something like this:

"Oct. 1, 1885.—I promise to pay John Smith \$30.00 for eleven swarms of bees now in my possession, providing I get honey enough from them to be worth the above sum. If I do not get the above amount of honey, what honey I do get I receive as pay for the care of the bees, and the bees are considered his property as in the start."

Now, even though the above is a pretty long lingo, there will be a good many chances for misunderstanding and hard feelings as it is. It is a fuss and bother too. Even if you get the agreement in black and white, sometimes so simple a thing as punctuation will leave a chance for a wrangle. I would not do it. Pay cash down for what you want to buy, or charge it on a book and show it to your neighbor, and ask him if the charge is right, or give him a note in the usual way. Jesus once said, "Let your communication be yea, yea; nay, nay; for whatsoever is more than these cometh of evil." Now, if we make our trades and swappings in the same way, wouldn't it be a very great escape from "evil"? You feel happier, your neighbor feels happier, and all the world looks happier to you when you pay cash down for what you want, or else "don't do it." One more idea. I have thought that unprincipled men sometimes purposely entered into complicated bargains with a view of having convenient avenues to slip out of what was plainly understood at the time as a bargain. Our short-hand writer suggests that some fishes sometimes roll the water on purpose to make a cover for escape.

SOME PLEASANT WORDS IN REGARD TO FLORIDA.

HOW TO PREPARE BEES SO THAT FOUR COLONIES
MAY BE CARRIED IN ONE HAND, LIKE A VALISE OR TRAVELING TRUNK.

ON the 24th day of November last I left my home in Indiana for Florida. I did not stop anywhere until I arrived at this beautiful place, on the Halifax River. I have hesitated for some time to write to you and your readers, fearing that my first impressions might be too highly colored and misleading; but after six weeks of close observation I find no cause to change them. I have not been in any way disappointed by the letters I have read of Florida, and I fully indorse the statements made by friend Hart, of New Smyrna, which is only eighteen miles south from Daytona.

I find the winter in Florida most delightful; the air is pure and balmy; flowers are blooming, oranges and lemons are ripening, and the bees have gathered honey and pollen almost every day since I have been here.

When I left home I took four colonies of bees with me, and succeeded so well that I think it might benefit others to know how I managed them. I use the Gallup frame. My hive is 12x12x18 inches long, inside measure, of very light and thin lumber. I made four boxes like my hive, only 6 inches long, across the bottom of which I fastened two pieces with notches cut into them to hold two frames secure in place. I then removed the hive I wished to

transfer, and put an empty hive in its place; cut a small entrance-hole in my box, and put it in the empty hive on the stand. I then selected two good frames with some honey, and put them with the bees on them, in the box, left the top of the box open, and closed the hive, and shook the rest of the bees in front of their old stand. They all ran in, and the next morning they were all where I wanted them, clustered on the two frames in my box. I carefully closed the entrance, and covered the top with wire cloth, and securely fastened the top of the frames. I now had them all on two frames in a box 12x12-6½ inches long, outside measure. These four boxes I fastened together with light hoop iron, with a handle on top like a gripsack. I now had a box 12x12-26 inches long, with open top, covered with wire cloth, containing four colonies of bees. They weighed about 50 lbs., and I could easily carry them from one train to another. In short, they were no more trouble to me than a common valise, and did not cost any freight. I kept them by my side all the time, and once a day gave them some water. They did not like to travel in the cars, and made some considerable noise; but when I opened them in Daytona there was not over a teacupful of dead bees in the four boxes. I made hives for them, and gave them empty frames, and they are doing well, building combs and raising brood.

On the cars, in hotels and depots, they were the cause of some friendly acquaintance and pleasant conversation. I met many bee-men, and they would notice the bees, and approach me, and you know how time flies, and how pleasant it is to have a friendly and interesting conversation.

I am very favorably impressed with the climate and conditions of Florida so far; but you know the old adage, "No rose without a thorn." I intend to stay here during the summer and observe further; if the summer should prove endurable, I will make this State my future home, and have my family come here; for, as I said before, the winter in Florida is most delightful. **HENRY STINEBACH.**

Daytona, Fla., Jan. 10, 1885.

THE HUTCHINSON'S HEDDON HONEY-BOARD.

HONOR TO WHOM HONOR IS DUE.

BRO. ROOT:—GLEANINGS is just at hand this Monday morn. After reading your account of what you saw at the Michigan State Convention, I want to remind you of the fact that I call my hive "Heddon's Langstroth hive;" that brother Hutchinson's queen-excluding honey-board that you already offer for 15 cts. each, is Hutchinson's Heddon honey-board. To make it clear of my inventions there must be no raised rim around the outsides, and the slots must not regularly break joints with the top-bars of the frames below. I think by the cut that the slots do not so break joints, but I think the one brother H. had at Kalamazoo last fall did, and such would be much better, as I know by actual trial. Where they do not, the bees fill the slots with comb, and they fill the small queen-excluding slot much worse than the ¾ double bee-passage slot, as strange as it may seem. I consider queen-excluding boards better of metal, and of no earthly use for comb honey at all. I have been there too.

To use two bee-spaces, outside of my inventions,

one must create the upper bee-space by virtue of the surplus receptacle, and *not* the honey-board. I think *not*; but for the sake of the argument, let us suppose that the narrowing of the slots, to exclude queens, an improvement. No one can honorably build an improvement on another's invention; and because of such improvement, rob the first of his improvements. Every civilized nation recognizes this in its patent laws, as you are well aware. I could have patented the raised rim and break-joint slots, but no patent could have been obtained on narrowing these slots so as to exclude queens. I have had a great deal to do with patents, and so have you had something to do with them lately, and you are undoubtedly aware of the above fact last set forth. I worked hard, experimented much, lay awake, and wore down my nervous system when others were asleep (as I should have been), invented, had these inventions laughed at, worked to get them before the public, and now, just as they are getting popular, I don't want them taken from me, neither in honor nor trade; and whoever does so, I want him or them to give me some reason why they do so, or admit that "might makes right," and call ourselves heathen. You may publish this if you wish.

P. S.—By error, you misjudged my circular regarding the bees we sell. See bottom of page 12, last three lines. We do sell pure Italians. Thanks for your friendly words. I consider the bee matter just something you overlooked. **JAMES HEDDON.**

Dowagiac, Mich., Jan. 19, 1885.

Friend H., we did not have an engraving made of the honey-board sent us by friend Hutchinson, for our crate of sections itself fixes the bee-spaces, so that honey-boards for the Simplicity hives would need to be as we figure them in the cut you mention. This cut is exactly the same honey-board we have been selling for years, with the exception of the perforations. Now, the idea of making the perforations with a circular saw, if I am correct, belongs to friends Taylor and Hutchinson; but as they are exactly like the perforations in the Jones zinc, only on a larger scale, so that they may be made in a wooden board, I can not see that there is much invention about it. If I am correct, making something of wood that has been formerly made of metal is not a patentable idea. Your honey-board must be something distinct and definite from any thing we have mentioned, and very likely your idea of having the spaces so arranged as to break joints in the brood-frames is going to be worth more than the queen-excluding arrangement. The one sent us by friend Hutchinson seems to have the perforations made at random, so I presume he did not have this point in view. I should say your honey-board, as you describe it, is, without question, patentable; and I do not believe any of our supply-dealers will offer it for sale without permission from you.—In regard to the matter of pure Italian queens, I now see that I made a mistake in running over your circular hastily, and hereby beg pardon.—As none of the cuts in your circular, nor any I have seen in print, show clearly how your honey-board is made, and its office, we will, with your permission, have a good engraving made as soon as the sample you say you sent us comes to hand.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

HONEY FROM BANANAS; MOSQUITO-HAWKS IN FLORIDA.

ONE of your correspondents says in GLEANINGS that either the rivers of California and Florida flow with honey, or bee-journals are sadly in need of a department for our friends who reliable to err in statements. We can not speak of any of the rivers but the St. John's, which is a pretty fair place we think. We have not been able to give our bees very much attention, and can not complain, though we can not give as big reports as some have done. Ours are all blacks, and we have averaged 40 lbs. per colony. The honey is here not in the river, but about as near as it could well be, for the bees collect it from plants and trees that grow in the water, besides a great many that grow on the land; but our industrious little workers have a great many enemies, and at times the havoc they work among the hives is dreadful. The dragon-fly, or mosquito-hawk, is one of the worst. Sometimes there seem almost as many mosquito-hawks as bees flying, and the way they do pounce down on the bees and carry them off is astounding, and there are many other enemies of which we will not speak at present.

We raise some bananas, but do not think much of them as honey-plants. The sweet fluid that drips from the bloom is not thick, but quite watery, about the consistency of the maple sap; nevertheless the bees seem very fond of it, and do not slight it when honey of better quality is abundant. When we get all those new appliances, drone-excluders and queen-excluding honey-boards, and if some invent, jive genius will invent some method whereby we can beat the mosquito-hawks and a few other bee-destroyers, then you may hear a big report from us.

Osteen, Fla., Jan. 12, 1885. MARY Z. RUSSELL.

FINDING DEAD BEES IN FRONT OF THE HIVE.

Why do so many bees die off in the winter? We have seen large numbers before our hives this winter, dead, and yet the colonies are very large, and doing well. It seems to be common among bees, and I should like to know what causes their dying off so.

MRS. WM. SWIGART.

Dixon, Ill., Jan. 9, 1885.

This question seems to come up frequently, my friend, and we have given frequent answers. I am inclined to think your bees are all right; and the fact that it is a large colony, and has been well, would seem to strengthen that idea. With a population of 40,000 it would be nothing strange if forty or fifty should die daily, from natural causes; and if you see these scattered about on the snow in front of the hives, you would be likely to think something was wrong. Of course, you would see most dead bees in front of the most powerful colonies. Is not this all the trouble?

FROST INSIDE OF THE HIVES.

I have my bees in Simplicity hives bought of you last spring. Each has 7 frames of honey and chaff-cushion division-boards, and chaff cushions over the frames; all are on their summer stands. During our coldest weather the frost collects on the ends of the frames and metal rabbets. I find the bees all col-

lect on one end of the frames near their entrance. Do you think it is caused by dampness?

Fairfax, Mo., Jan. 12, 1885.

G. M. SHAVER.

I think there is nothing wrong about your bees, friend S. The frost is the perspiration from the cluster, and it is almost always found in hives made of a single thickness of boards, unless the colony is so very strong that it fills the hive so completely as to keep the frost out. When the weather moderates, this frost will melt and run down, often running out at the entrance. If it collects on unsealed honey it dilutes it, and sometimes we have sweetened water running out of the hives. As a general thing it does no particular harm, unless so much ice collects as to wet the bees, or dampen their stores. The remedy is to use a chaff hive, which we always recommend for wintering, although bees usually winter all right in Simplicity hives.

HONEY FROM THE ISLAND OF CUBA.

I send you by this mail a sample of campanilla (or bellflower) honey, which is just as thrown from combs to-day. Please sample it and report. Will give you final report after a while.

Cuba, W. I., Jan. 8, 1885.

Thanks, friend O. The sample of honey sent is of a beautiful light straw color, very transparent, of good body, and of a fine aromatic flavor that we should think entitles it to a place on an equal with either basswood or clover. We should be glad to hear further reports from you.

MY BEES AND CARP.

I have three stands of bees, all in chaff hives, put away with chaff division-boards, and upper story with sack filled with chaff. I got only about 40 lbs. last summer. The drought cut short the white clover. As to carp, I built a small pond, I think about 1880. It contains about $\frac{1}{2}$ acre. I received from Washington about 16 German carp; introduced them in fall of 1881. I did not see them any more until last June, when I discovered my pond was alive with small fish. I commenced to feed them, and also advertised them in our county paper, and succeeded in selling 1450, from one to two inches long, and have a goodly number yet remaining in the pond.

NOAH HORN.

Roseville, Ohio, Jan. 14, 1885.

WHAT TO DO WITH HIVES CONTAINING OLD BLACK COMBS, ETC.

In the spring we had 12 stocks, which have increased to 20. In the fore part of the season, bees did pretty well. I took about 300 lbs. of extracted and 125 lbs. comb honey. My hives are all frame, of my own make. Most of the comb honey was taken from two-story hives, the second story being about six inches deep, containing frames that hold about 5 lbs. This is the most satisfactory size to my neighbors, and are handy to extract from. I have sold my whole crop right at our door, at prices ranging from 10 to 15 cts. per lb. I use a home-made extractor, made out of a barrel, which cost me \$134, besides my own labor.

I have several hives in which the combs are so thick and black that it is unfit for use; how am I to get rid of it without sacrificing the brood? What would you do with light swarms at this time of the

year? I have not the time or money to experiment, so please give me your ideas of the matter.

E. W. OSBURN.

North Adams, Mich., Oct. 13, 1884.

Transfer those old hives, friend O., and save only the good comb, or that containing brood. If there is brood scattered about in poor unshapely comb, fasten it into frames so as to keep it until the brood hatches out, then throw it away. Most of the transferring done now, I believe, is so managed that only the best of the old comb should be used, and the hive filled out with the modern kinds of combs built on fdn. placed in wired frames. If I had light colonies in October I would endeavor to take them through by feeding; if they are too weak to be fed, double them up; and I do not know how you can manage it without taking some time or money. Uniting can be easily done in the cellar, but you will probably lose one of your queens.

FRIEND FOX'S BEE-FEEDER; HOW TO MAKE IT.

I take a Langstroth rack to the tinner, and have him make me a tin box the exact size of the rack, with the exception of the depth, which is 6 inches instead of 9½; put a ½-inch tin thimble in the center of top-bar, to fill from; insert a cork after filling; put in the bottom, four tin gauze-thimbles, these to be filled with sponge; leave quite a bunch for the bees to cluster on. When filled, raise the cover and insert the feeder in center of cluster, and the bees will empty it in a short time, the outlet being in center of cluster, and there being no danger from robbers, and no daubing of hive, and no escape of heat from the hive.

Hillsborough, Wis., Jan. 5, 1885.

E. FOX.

The new feature in this feeder seems to be in arranging it so the feed will slowly ooze through bits of sponge, and these pieces of sponge are held in place by wire-cloth tubes, so that a large number of bees can have access to them. By the time you have fed heavily for a day or two, I am inclined to think the bees would build a comb covering the sponges all up. One trouble I have found with similar arrangements is, that when we are filling many hives it is difficult to see just when your feeder is full, unless you pour very carefully and slowly.

F. J. FLORY'S SECTION-CLAMP.

Get four pieces of stuff, cut the same shape as the hollow-angled sample sent, place 2 of these with hollow side up, put in a 1-lb. or any sized section near the middle, then put the other 2 pieces on the top of the section, and tack all with your very small wire nails, then you will see that you can slide in other sections the same size till you fill the clamp to whatever length you require. Another lot of sections in same shape will fit over these, and you can tier up as high as you like, and have a bee-space between. When the top is filled you can reverse in a moment, if necessary; and if only some are filled you can slide them out and put in others. The small wire nails can be drawn out with the point of almost any knife. By tiering up in this style there is always a ½-inch space between tiers, and by cutting your clamps the required length you can put in your tiers alternately endwise, or across, as you desire.

I think you, better than I, can appreciate this

idea, which I feel sure is very valuable to those producing comb honey. All credit is due to F. J. Flory, of Lemoore, Tulare Co., Cal., who so unselfishly presents it to his brother bee-keepers, without taking any patent on it.

GEORGE HOBLER.

Hanford, Cal., Jan., 1885.

The sticks sent us by friend H. are made exactly in the way we make chaff-hive corners, only they are sawed out from a ½ board. They are sawed so that the thickness of the stuff is ½ inch. This will leave the sections about ½ inch from each other, and a tier of them can be handled as a single box. Now, although these ½ bee-spaces have become quite fashionable, it seems to me they are quite objectionable. The lower tier of sections must have a bee-space under them. Why any more bee-space? It is true, it enables us to handle six or eight sections as one box, but how are the ends to be closed? The same thing has been a long time in use, only folded tins were used instead of the wooden troughs. The folded tins would probably cost the same, but they would reduce the bee-space to little or nothing. It seems to me I would have a little square board at each end, and then these long boxes made up of sections can be sent to market if desired. The idea may find favor with many of the brethren, and we thank friend Flory for suggesting these V-shaped clamps which can be so cheaply made.

TREATMENT OF FOUL BROOD ON THE CHESHIRE PLAN.

We extract the following from a circular just received to-day.

"Treatment of '*Bacillus alvei*,' or Foul Brood, by absolute phenol, according to the 'Cheshire' method.

ABSOLUTE PHENOL.

To obtain it of the desired strength, dissolve 40 grammes of absolute phenol in crystals, in 10 grammes of water.

PHENOL IN SOLUTION, FOR TREATING THE DISEASE.

Put one part by measure of the above mixture in 20 parts by measure of water; shake carefully until the oily deposit has disappeared completely, and take great care to use no vessel that is not perfectly clean.

MEDICATED SYRUP.

Put one part by measure of the above-named solution in 20 parts by measure of syrup.

TREATMENT.

The following instructions are of the greatest importance, and should be strictly adhered to:

Reduce the infected colony to the number of frames that the bees can cover, by putting any superfluous frames behind the division-boards, and then commence to feed the medicated syrup, which must be fed regularly every evening. If the bees accept the feed in the ordinary manner, all is well; if not, it must be spilled into the empty cells of the brood-chamber (beside or above the brood), keeping the hive quite warm so as to encourage breeding. Do not remove the queen unless it is suspected that she is sick. If there are enough bees to raise brood, the most severe cases will soon yield to this treatment. As fast as the bees need a larger number of combs, give them one of the infected combs placed behind the division-board. A rapid raising of brood is most important: the quicker this is accomplished, the quicker will be the cure. If at the end of some days the bees take the feed well, it can then be given in bottles on top of the frames in the ordinary manner.

With a view to facilitate a trial of the 'Cheshire' cure I have had small vials, prepared which contain 40 grammes of absolute phenol in crystals (the purest obtainable), and will mail them anywhere in the United States on receipt of 50 cents by postal note or stamps.

This quantity is sufficient to prepare 23 quarts of medicated syrup—more than enough to treat several colonies.
 Germantown, Pa. ARTHUR TODD.

The above is a wonderful invention, if it be true; but if I am correct, several of the friends report, in the *British Bee Journal*, failures after having tried it faithfully. If foul brood can be cured by simply feeding bees medicated syrup, it would be worth thousands to our country. Please pardon me for being a little skeptical; but the truth is, I can not quite see how cells containing diseased larvæ in a putrid state are going to be cleaned by feeding the bees medicated syrup.

RAISING PLANTS FOR CARP.

Somebody sent us the following, on a little scrap of paper:

The Fish Commission at Washington had been informed that the plant called great bladderwort would furnish excellent food for young carp. They procured a large number of plants, and had them set out in the carp-ponds. The plants came high, but, as they were good for the fish, they had to have them. Then they watched patiently for the carp to eat the plants. They had not watched long till they discovered that the plants were eating the fish. The small bladders growing on the leaves caught the small fry in great numbers.

Well, I am sorry the speculation turned out the way it did; but there is one thing I am glad to know, and that is, that the Fish Commission are so eagerly looking up this matter. A plant that will grow rapidly in the water, and would be eagerly devoured by the fish, is the next great thing to be desired.

AN AUSTRALIAN LETTER.

I have been diligently studying A B C; have made my start as a bee-keeper, with 5 hives purchased in Sept., which is our first month of spring. They were in *old* boxes, and, I dare say, had been in use for some years, as the comb was mostly black with age, and very tough (I suppose with the webs of repeated brood-rearing).

We succeeded in transferring them to Langstroth hives, and supplied them with comb foundation. We used only about 2 frames of the brood-comb, as there was, in my opinion, too large a percentage of drone-cells among it. We got very little honey from these hives, the cause being attributed by me to the immense number of drones each hive contained.

I may say here, that I have thought about bee-keeping for a long time past, and have read nearly every thing on the subject that came into my hands, and it has now turned out that my reading was mostly of obsolete works. It was in the *American Agriculturist* that we first heard of A. I. Root and of Quinby and Prof. Cook. I would have made a start with 20 or 30 hives if it had not been for your earnest admonition to the contrary, the value of which advice I now very much appreciate, and to its neglect, an apiarist of my acquaintance, owning about 100 hives, attributes his utter failure. Our bees are common brown or black bees, but I intend to Italianize them as soon as possible, beginning with the hive I am expecting at my house. I can procure a tested Italian queen, second grade, \$4.80; first grade, \$12.00. I shall start on a second-grade queen, following A B C, and afterward I will try the first grade for queen-rearing on my own account.

STEPHEN MALLARKEY.

Sidney, N. S. W., Australia, Dec. 2, 1884.

JACKSON'S SOLAR EXTRACTOR.

I here give you a description of a solar-heat wax-extractor, as made and used by Mr. A. Jackson, of King's River, Fresno Co., California. Take two boards, 1 x 16 inches, 4 feet long; nail carefully at angles, making a V-shaped trough; put on ends, then line with tin, carefully soldered. Put a honey-gate at one end near the bottom; put cleats around the outside, near the top, to rest the upper box on. The upper box is made of 1 x 6 lumber, to fit on the cleats bee-tight. Before nailing together the top box, have 2 saw-cuts put in it all around, the first one inch from the top, the second 2½ inches from the top. Now nail sides to one end, and slip glass into the saw-cuts, and screw on the other end. Now make a frame, to fit about 1 or 2 inches inside the trough; on this frame tack burlap, and put in place; put your cappings, or combs to be melted, on the burlap frame, then put on your top, and give the whole a lean endwise, and face to the sun, where, if hot, your honey and wax will soon pass through the burlap, and the honey can be drawn off by the gate, and more material added, and the wax taken away at leisure. When the burlap becomes clogged by refuse it can be taken off and boiled, to secure any wax which may remain, and another can be tacked on to the frame. This has proved very effective here. GEORGE HOBLER.

Hanford, Cal., Jan., 1885.

Thank you, friend H. The above solar wax-extractor is very simple, and easily made, and I will at once have one gotten up; and if it works as well as I suppose it will when the weather is warm enough, I will try to remember you and friend Jackson a little more substantially. May be such an arrangement would work in California, on account of the more intense heat of the sun, when it would not here. I should hardly think a 1½-inch space were needed between the two lights of glass, but very likely friend Jackson has experimented on this, and knows what is about right.

BEEES WORKING ON RED CLOVER.

In regard to bees working on red clover, I see some say that the blacks do not. In some seasons they do, in others they do not. When the large clover grows to a great size, the bloom opens so they can crawl down far enough to reach the honey, otherwise not.

I have 33 colonies; no swarms this season; rather poor season for honey. JNO. JACOBUS.

North Urbanna, N. Y., Jan. 2, 1885.

EPILOBIUM, OR WILLOW-HERB.

This is in no sense a fireweed. As you call for any light that any may be able to shed upon the above plant, I will say that I have observed it (whenever I went north), and corresponded with several about it for the last six years, and I have known it to be a fine honey-plant; but I never sowed or planted a seed of it, for I feel quite sure it can never succeed so far south as our latitude. Now, if you will study it further, both by botany and correspondence, with those living north of 44° north latitude, I feel sure that you will arrive at the same conclusion I have, that we can never cultivate it successfully as far south as we reside.

Dowagiac, Mich., Jan., 1885. JAMES HEDDON.

Thanks for your timely reminder, friend H. While I think of it, all reports from the willow-herb have been from Maine, or the northern portions of Michigan, and may be

it would not grow and bear honey here. But this we do know, that the *Gaura biennis* bears honey most amazingly in our flower-garden. And, by the way, there does not seem to be anybody able to furnish us seeds. There is one consolation, however: as the seeds grow themselves when self-sown, we shall have a lot of them in the spring, from the seeds dropped off in the garden before I got up early enough to know what an acquisition we had right under our "noses."

KEEPING THE BEES AWAY FROM THE CIDER-MILLS AND CANE-MILLS.

What, in your opinion, is the best method to keep bees away from our cane-mills and evaporating-pans in the fall season, when honey is scarce in the flowers? How would it do to feed sugar syrup a few rods from the hives, in an opposite direction from the mill and evaporator? I have some coolers not in use, made of wood, sides and ends, 6 ft. x 3 ft. x 6 in. Could I not utilize these for feeding, by placing narrow strips of wood on the bottom, for the bees to stand on while taking the syrup? Should this plan be successful, it strikes me it would be economical, as the season for syrup-making comes just at the time (in our section of country) when the flow of honey generally ceases, so you see the syrup fed would be put up for winter stores. And should this plan work for the sorghum-maker, it will also prove advantageous to the cider and vinegar manufacturers. T. J. CROSS.

Shiloh Hill, Ills., Jan. 14, 1885.

Friend C., I have made a great many experiments to draw bees away from the cider-mills with sugar. You can not do it unless you feed an enormous amount of sugar, and in doing this you will make a regular row all over the neighborhood. They are too eager for the cane sugar; and after you make it so thin with water that it is not much of an object, it soon sours, so there is considerable expense attending the care of such a feeding arrangement. We succeeded much better with grape sugar, for they did not care enough about that to get into much of a robbing mania. I think by far the cheapest and pleasantest way will be to cover your cider-mills and sorghum-factories with suitable sheds, having all the openings protected by wire-cloth doors.

THE YUCCA, OR SPANISH-BAYONET BRUSHES, USED FOR BRUSHING BEES OFF THE COMBS.

In one of the barrels of brushes I send you to-day, near the top you will find a photograph of a yucca, from which these brushes are gathered. Seven years ago a gentleman who resides at Pasadena brought it from the mountains, and set it out in his orange orchard. From that time until the past summer it received the same care and attention that his orange-trees received. The result of the cultivation can be seen in the photo. Last spring it started to throw up its center shaft, or flower-stalk; it was eagerly watched, to see what height it would attain. Just how high it was I do not know; but as nearly as I can remember, as I stood beside it, the top of the leaves that surrounded the flower stalk were as high as my shoulders, and I am just five feet and eight inches. You can also judge its height by comparison with the bearing oranges just back of it. The flower-stalk is the growth of but two or three months; and as it stood there with

its top completely covered with these creamy-white flowers it was a sight that is seldom seen. While in bloom it was visited by hundreds from all parts of the county. I went nine miles and back just on purpose to see it. This species of the yucca (*Yucca baccata*) dies after it blooms; the remains of this one were taken up and placed in the public library at Pasadena, where it can be seen by any one who will take the trouble to call.

Now, friend Root, can't you afford to give the readers of GLEANINGS a view of this magnificent plant, and attach the above description to it? Note, also, in both GLEANINGS and price list, that the fibers of the yucca-brushes are apt to get pressed out of shape in shipping; if they are thoroughly wet you can place them in almost any position; if kept so until they are dry they will stay in that shape.

In the barrel of 1125 is one of the leaves as it is taken from the flower-stalk of the yucca, "with the thorn and all." I think you will be pleased with the brushes, as they are as fine a lot as I have ever seen. There are a few that are below the standard, but these are thrown in without counting. I would suggest that the brushes be left in the barrels until they are sold, as they will keep better in that position than in any other. See how nicely they pack in barrels. W. W. BLISS.

Duarte, Los Angeles Co., Cal., Dec. 8, 1884.

Thanks, friend B., for telling us where our bee-brushes grow. I would have the beautiful plant engraved, which you send, but it would be pretty expensive; and as it is not strictly a honey-plant, I think it would hardly be best. We present below an engraving made several years ago, of the same plant; but of course it is not nearly equal to the one you have shown in the photograph. Perhaps I might inform the friends, that by buying these brushes in such large quantities we can now sell them as follows: 5c each, 35c for 10, or \$2.50 per 100. If wanted by mail, add one cent each for postage.

THE YUCCA, OR SPANISH BAYONET.

LUMPS OR CAKES OF ICE INSIDE OF A CHAFF HIVE.

Yesterday I examined the bees in the one-story chaff hives which I received from you, and found bees in splendid condition, covering frames nicely, except in one hive, out of which I had taken last fall one frame with honey, and not filled up the space thus made, it being an outside frame. That space was $\frac{1}{2}$ inch thick with frosty evaporation. Had I better scrape it off and put a frame with honey in its place? W. A. THOLEN.

Port Washington, Wis., Jan. 17, 1885.

I would take out the ice if I could get it out handily, friend T., and then move up the division-board so as to occupy this space, and fill back of it with chaff. I should think the colony, however, that contained the ice was too weak to fill the brood-nest properly, so as to expel the moisture. Are your chaff cushions over the cluster sufficiently porous? This is one reason why forest-leaves thrown loosely into the upper story have been suggested. The dampness would pass up through them, and go out at the ventilators, unless the colony were very weak. In that case, ice might collect on the leaves; but as soon as the weather becomes warm enough, it would melt and evaporate, the moisture being carried out by the current of air generated by the cluster of bees beneath it.

FRIEND WILLIAMS TELLS US A SURE WAY TO CIRCUMVENT THIEVES.

Let me tell how I manage to keep thieves away. For the last seven years, I kept a cupboard under the smokehouse shed, with honey in it. I let every one know it was there; some were too well bred to ask for it and some bread to eat with it, and I would rather they would take it than interrupt the hives; and if any one wanted honey in sickness, it was always ready, without money and without price, and they came right along and got it. They knew we kept some to give away to the sick; and when they offered pay, we told them no; they were welcome to it. I don't know whether that is the best way or not; but that is the way we did, and will do so again as soon as we get fixed in our new home, though there is but little fixing to do, as I am succeeding W. C. Pelham in the bee business, only not in fdn. mills. We are partners in bees and honey.

Maysville, Ky., Jan. 5, 1885. M. L. WILLIAMS.

Thank you, friend W. I believe your plan will work every time. In fact, I am under the impression that it will be cheaper and surer than shot guns with strings tied to the trigger. I think, however, I would let people pay for the honey when they want it for sickness, if they want to do so; but let all your neighbors know for miles around, that if anybody has not the money to pay, or would rather steal it than pay for it, they can have it for the asking. People who have a reputation for generosity like this, seldom have their property meddled with by thieves.

CLEANING OUT SMOKER-TUBES WITH A HOT WIRE.

When my smoker needs cleaning I have not time to scrape the sticky soot from the tube; but as "like cures like," heat fills the tube, and a hot wire or small rod cleans it out "quicker."

A TWO-PRONGED WIRE NAIL WANTED.

I should be pleased to be favored with the address of manufacturers of the wire nails you sell, for the

purpose of having staples made of small wire, to fasten wire cloth to queen-cages, door-frames, hives, and to be used in making pint and quart berry-boxes. Please look at a berry-box, and see how the grain of one part of box runs across the grain of the other part, and you can judge how much stronger the staples will make the box, as well as lessen the liability of having one of those rascally cut tacks drop into the cup of a large raspberry. We buy cut tacks at 60 cts. per lb. The wire staples will have to be cheap to compete; but when we see how much better they are than tacks, possibly we can afford them. If you will ask the manufacturers to make them, allow me to suggest the No. 21 wire, prongs of staple to be $\frac{1}{4}$ inch long, and the main part of staple to be $\frac{3}{8}$ inch long. Such staples will be just the things for fastening building-paper, etc. H. M. HAWLEY.

Terre Haute, Ind.

Thanks, friend H. Somebody has once before mentioned that a stout iron wire of the proper size, bent so as to conform to the curve of the smoker-tube, would, when heated red hot, clean the tube out in a twinkling.—Two-pronged tacks are already in the market, but they are not strictly the two-pronged wire nail. Our wire nails are made by the H. P. Nail Co., Cleveland, O., and by Albert Field, Providence, R. I. From the large quantities of wire nails that we purchase yearly, we are enabled to give better retail prices than they would probably give any of our customers. If I am correct they do not sell less than a 100-lb. keg of any size. I will send your letter to them in regard to the two-pronged wire nails wanted. I agree with you, that it would be a desirable thing for basket-work.

WHAT IS IT BESIDES WAX THAT HONEY-COMB IS MADE OF?

I find that when all the wax has melted out of it the cells retain their perfect shape if not put out of shape before the heat is applied. G. HOBLER.

Hanford, Cal., Jan. 10, 1885.

Friend H., if you are talking about brood-combs, you probably mean the cocoon that is added to every cell every time a bee is hatched in it. But aside from this, it is claimed that the cappings of the purest comb honey do not all render into wax. What this other matter is, no one has yet been able to tell, so far as I know. I think it was friend Bingham, of Abromia, Mich., who said that a pound of clean cappings from comb honey would not make nearly a pound of clean white wax.

STILL ANOTHER INVENTION FOR CLEANING SMOKER-TUBES.

I have been much annoyed by the curved air-blast tube in my smoker getting choked by a vile mixture of soot and pyroligneous tar. The only effectual cure I have found for it is hot iron. Take a piece of large wire, say one-fourth inch diameter, curved at one end to fit the curve of blast-tube, and sharpened with a file about as you would a cedar penell; heat this to a red or even white heat, and pass it quickly through the nozzle of the smoker into the blast-tube and out again a few times, and, presto! it is as clear as a whistle. A small number of wire will not do well, as it gets cool too easily. With care not to burn the valve of the bellows, you

will find it a "sovereign remedy." The wire, well heated, is a sort of lamp, giving light by which to find the end of the small tube. This simple device may keep some of your A B C scholars from doing just what I did before I thought of it; viz., taking off the leather from the bellows to get at the tube to clean it; for I found the sticky stuff would not yield to the persuasions of any sort of swab or scraper I could get up. W. L. ANDERSON.

Ninety Six, S. C., Jan. 8, 1885.

Thanks, friend A. Our apiarist has just found a smoker, the tube badly clogged up with this black tar, and he says although he did get it cleaned out with a hot wire he had to heat the wire three times, and he thinks it took more time than the little wire hook we recently illustrated. We have found no trouble in cleaning any of the tubes with this.

REVERSIBLE FRAMES AND REVERSING DEVICES.

THE ABSORBING TOPIC OF THE DAY.

FROM the number of letters and number of devices that every mail brings, it would seem this is now the principal topic of interest. We will begin with the plan adopted by friend Heddon:

HEDDON'S REVERSIBLE FRAME.

Above we give an illustration of the frame preferred by friend H., and underneath a description of it, copied from the *A. B. J.*:

I will give my reasons for preferring the style of frame illustrated, above all others that I have yet seen described. At a glance, almost any one can estimate the extra cost of constructing such a frame. I believe this frame to be worth several times more than the extra cost, more than the common non-reversible frame for only once reversing for the purposes just mentioned, if for none of the advantages hoped to be gained in the ways spoken of in the first part of this article.

Again, I much prefer this frame to the old style, even if I never reversed it at all: 1. I am not troubled with sagging top-bars; and the outer bar, the one which governs the uniformity of the bee-space, or Langstroth shallow air-chamber below the honey-board, never sags. If the inner top-bar sags, it does little harm, and when reversed, the sag is thus converted as it straightens back to place, and the new top-bar (just from the bottom) will not sag. In reversing, I either shake off the bees or revolve the inner frame very slowly. I generally prefer to shake off the bulk of the bees, and I have found that on an average I spent five minutes to each hive (counting opening and closing) in performing the reversal of all the eight frames. Bits of comb and propolis bother but little, as the sharp corners of the wood pieces shave them away like a pair of shears.

2. It will be noticed in that while the top and bottom bars of this frame form "bee spaces" with the hive the same as other frames, the ends do not, and in this difference I find an improvement. It will also be noticed that the short end-piece is tapering, regarding its thickness. Now, the whole end while in the hive comes, top $\frac{1}{2}$ of an inch away from the hive end, the bottom of the short piece $\frac{3}{4}$ of an inch, and all below that, $\frac{3}{4}$ of an inch away. This large opening, while it greatly facilitates in the rapid and easy withdrawal or insertion of the frame, is in no danger of the bees building combs

in even so large and handy a space where such space is *no higher up* than shown in the illustration. While this frame is of slightly less capacity or surface than the standard Langstroth frame, it has a greater brood capacity when reversed, and fits the same hive as the standard.

The above frame certainly possesses some very marked advantages—cheaply made, strong, quickly reversible, without any loose pieces, and will be one of the nicest frames to handle, so far as lifting it out of the hive is concerned, that has ever been constructed. In fact, our British friends have adopted and used, to a considerable extent, a frame made smaller at the bottom than it is at the top, to be set in a hive with sloping ends, just to accomplish what friend H. has with his reversible frame. Now, if we were to build new frames right out, I do not know but that the above management is the best thing we can get; but if they are to be used in the same hives we have been using, a frame of smaller dimensions must be adopted. We have less space for honey and brood, and our old combs must be either cut down, or thrown away. A good deal of waste space is also occupied right over the brood-nest. In fact, I do not know where friend H. is going with an extra top-bar and honey-board, and two extra bee-spaces. I do not really gather from the description, whether a bee-space is to be left between the two top-bars or not. Will friend H. tell us in regard to this?

OTHER REVERSIBLE FRAMES.

Last month we spoke of an invention of Mr. Nimshi Nuzum. Well, so many other new things have come up since then, that we will not have an engraving made of it. It is substantially the same as the Howes reversible frame, illustrated and described last season. We give the cut again, however, to illustrate reversible frames in general.

HOWES' REVERSIBLE FRAME-SUPPORT.

Well, friend Nuzum's device was almost exactly like the above, only it was made of one piece of metal, without soldering. We found the blanks could be cut out very cheaply; but when it came to folding them we found it a pretty slow process. The Broers frame, mentioned just before we went to press, is also made of one piece of metal; but instead of being hinged as in the cut above on the *flat side* of the end-bar, it has two arms, and is hinged in each *edge* of the above end-bar, making a sort of stirrup arrangement, or like a swing, as it were, swinging on *two* pivots. The corner is much like the corner in the cut above. Now, in both or all of the above arrangements, a good deal of accuracy is required, for the supporting arm must just slip over the corner of the frame. If it should be too long it would look awkward, and fit badly; and if it were too short it would not slip over at all. This

would be quite an objection in adapting it to the various frames already in use.

And here comes in friend John McGonnell, of Mill Village, Erie County, Penn., with an arrangement made of one piece of metal, no solder required, that is like the Howes frame shown above, but does not go over the top-bar at all. We thought once it was ahead of all others, and made a modified model, from which the engraving below was made.

McGONNELL'S FRAME-REVERSING DEVICE, SOMEWHAT MODIFIED.

Well, this works nicely, and it does not matter whether it fits exactly to the frame it is intended for or not; but it can not be made without soldering, and it has, also, the sharp corners that have been objected to on our metal-cornered frames. The supporting arms are also liable to get bent, unless made of quite heavy metal. We figured on this a day or two, and then Mr. O. C. Thompson, of Emporia, Kansas, sent us an arrangement made entirely of stiff wire, that does all that McGonnell's device does—makes a nice corner to handle—nothing to hurt the fingers. It is, however, hinged by a single rivet, like the Howes arrangement.

Well, now, friends, from all these we have made one of wire, that will reverse as quickly as the Heddon arrangement; can be put on to any frame in an instant, almost, without screw or tack or wire nail, and yet requires no great accuracy. It is made of a single piece of wire, and swings on two pivots. The arms are made of stiff wire, bent a good deal like the arms of our metal-cornered frames. We are too late for engravings this month, but the arrangement looks a good deal like the loop on the top of an old-fashioned door-key—two folded ovals of wire, as it were. The stem of the key would represent the arm of wire that they swing on. The corner of the frame comes between these two ovals. We put our frames together, using all bottom corners. After the frame is done, the wire-reversing attachment is put on by making an awl-hole through the center of the end-bar, boring through edge-wise. If you take a frame in your hand in the ordinary way, holding it by the supporting arms, one in each hand, you can reverse the frame in less than a second, keeping your fingers hold of the supporting arms. Of course, something may come in still ahead of this; but the prospect seems to be that the invention is to be the work of a great number of minds. It is a little remarkable, that the same thing exactly comes from individuals far remote from each other; thus, J. W. Martin, Greenwood, W. Va., sends a model *exactly* like the Broers model.

Now, you know I have commenced paying for such devices as pleased me—for such as I wanted to use; but I really can not tell how to pay in regard to this reversible-frame business. What we have at present decided on

is unlike any thing sent in to us. I have given friend Hutchinson \$25.00 for the idea of his perforated honey-board. I have also given friend Heddon \$100.00 for the privilege of advertising his hives; and I have agreed to furnish them at his prices—no less. If I understand it, friend Heddon is willing that all should make his arrangements for their own use, but he does not want any persons to advertise "Heddon's hives and fixtures" unless they make some arrangement with him, as I have done, for the privilege of so doing. This is certainly no more than just and right; and any bee-keeper who says in his catalogue or price list that he will furnish "Heddon's hives and fixtures," without making an arrangement with friend Heddon, ought to be publicly held up. I told friend H. that, if he preferred, I would not make any of his things at all, or that, if agreeable to him, I would give him \$100 for the above privilege. Another thing, friend H. is to fix the price on his own goods. If he charges more for them than you think they can be made for, it will leave you a margin for very nice workmanship, and I do not believe anybody will feel hurt if you do this.

A great quantity of inventions are being sent in to me daily, and sometimes some of the friends talk hard because I do not think as much of their inventions as they do. Please remember, I agree to buy only what I want, or what I think I want. If I am dull, or stand in my own light, it is my privilege to be and do so. All I agree to do is this: Whatever you send me that I make use of, I am willing to pay for.

NOTES AND QUERIES.

FROM 29 TO 54, AND 300 LBS. OF HONEY.

I PLACED 38 colonies and 3 nuclei in cellar; they are all right. I commenced last year with 29; increased to 54, mostly natural swarming; lost 3 in the fall, drone-breeder; sold 3, and brimstoned 30. I offered them for the value of hives and honey, but could find no purchaser. I extracted about 3000 lbs. box honey, 125 full ones, and 64 more or less full; extracted 34 lbs. of wax from cappings.

Recapitulation: In the spring of 1882, began with 4 box hives; have now 38 colonies, 3 nuclei, and about 500 spare frames, the greater part built on foundation. Thanks to GLEANINGS.

Milwaukee, Wis., Jan. 2, 1885.

R. BRUNN.

[It seems to me, friend B., you could have found a purchaser by advertising a little. I may be mistaken, however. Brimstoning 30 colonies seems to me to be a pretty saluting report in this line of progress.]

THE HONEY-PEAS.

I got three pints of honey-peas from the five-cent package of seed you sent me. I did not see any bees at work on the blossoms. S. H. HUGH.

Saybrook, Ohio, Nov. 19, 1884.

[Perhaps your plat was too small, friend H., for the bees to find them. Ours made a magnificent growth of foliage, but "nary a blossom," although they had the whole season to get at it.]

AGE OF DRONES.

How old must drones be before they are capable of fertilizing a queen? J. G. SHARP.

Rocksidge, Can., Jan. 12, 1885.

[If I am correct, friend S., they need to be only old enough to fly outdoors, and they usually take their flight at the same time the young workers do, so far as I have observed—say when they are two or three weeks old.]

MAKING SHEETS OF FDN. WITH A WOODEN WHEEL.

On page 56, Feb., 1880, you dip sheets of wax "very thin and even" "to the best advantage with a wooden wheel about 2 ft. in diameter." Why not use such a "wheel" altogether, instead of dipping-boards? IMKER.

Philipsburg, Can., Jan. 14, 1885.

[Friend I., we abandoned it because it was, like a thousand other things, "too much machinery." The sheets were too long to handle easily, and the girls with the dipping-boards would run right away from the wheel. I believe the wheel has been universally abandoned, unless by our friends Vandusen, of Sprout Brook, N. Y., who make the flat-bottomed fdn.]

CIRCULARS RECEIVED.

A 4-page circular from C. L. Brooks, Deansville, N. Y.; supplies generally.

M. S. West, Flint, Mich., sends out a one-page circular of Simplicity hives and L. Frames.

A 4-page circular from Miss Alice Fisher, Anna City, Ill. Poetry. Printed at this office.

A 20-page price list from F. A. Snell, Milledgeville, Ill. Specialties, the Eclipse bee-hive, Italian bees, queens, etc.

A 20-page circular from E. Armstrong, Jerseyville, Ill. Specialties, Standard Crown bee-hive, and bee-supplies generally.

J. M. Killough & Co., San Marcos, Texas, send out an 8-page circular, printed at this office; specialties, bees, queens, and supplies generally.

A 3-page price list from J. C. Newman & Son, Peoria, N. Y. Specialties, sections to nail, separators, section honey-racks, and Bingham smokers.

An 8-page price list from F. L. Dougherty, successor to Dougherty & McKee, Indianapolis, Ind. Specialties, bees and hives, and other supplies.

A 16-page price list, M. Richardson, Port Colborne, Ont. This circular contains much valuable information; gives the cut of one-story chair hive, and Canadian supplies generally.

An 8-page circular from Dr. S. F. Haskins, Hudson, Mass. Specialties, poultry, Italian bees, and Simplicity hives. This circular folds up into a sort of envelope, and has a picture of an incubator on the outside.

G. B. Lewis & Co. send out a nice new circular, reduced prices on hives and sections, and quite a lot of new "pictures." So many of the pictures in our price list have got to be so old and stereotyped that something a little new is refreshing.

D. A. Jones sends out a 32-page price list—lots of pictures, and much valuable matter. Friend J. is up to the times every time, you may be sure. He has a little book on foul brood, its management and cure. In the latter part of his circular are terms to students in bee culture.

Watson & Thell, Brooklyn, N. Y., send out a circular that looks a little as if they were not well posted in regard to modern bee culture. Prices of hives, \$50.00 a pair, etc. They quote "M. Quinsby" quite a little, and father Langstroth, who might lead one to think his work was in harmony with Langstroth and Quinsby. Perhaps they have always lived in the city, and are not posted.

A. C. Kendel, Cleveland, O., sends us his annual 32-page price list of seeds, etc. On the last leaf he mentions hives and beekeepers' supplies; and clear down in the last corner he gives prices of German carp for stocking ponds. Prices are from \$7.00 per 100 to \$1.00 per dozen. Friend Kendel has been the means of selling a good deal of honey for many of the brethren, and we think you will find him a nice man to deal with in every shape and manner. By the way, friend K.'s circular is quite instructive in a good many ways. For instance, under the head of "birds" we find ant-eggs, \$1.00 a pound; fish for gold fish, 10 cts. per box; bird lime for catching birds, 20 cts. a box; and last of all, meal worms, 25 cts. per 100. May be friend K. would like to be stuck up on the latter.

Our old friend Oliver Foster, Mt. Vernon, Ia., sends out a very pretty circular, printed at his office; specialties, bees in the U. S., and melted wax tin machinery. Friend F. offers a round of bees in April for 30 cts.; the same in July for 50 cts. Now, at these extremely low prices his bees ought to be all bought up, even before he gets started. I shall be very glad if he can stand the rush of business at these prices, but it seems to me he will have to give it up. His circular contains much valuable matter, and is worth sending for. I should say it was a pretty expensive business, selling a round of bees in April for \$2.00, let alone offering them for 30 cts.; but friend Foster is good for all he agrees to do, I believe, so those who give him their orders before he says "hold on" will be the lucky ones.

CONVENTION NOTICES.

The second annual picnic of the Northern Michigan Bee-keepers' Society will be held at the apiary of F. A. Palmer, near McBride, the last Thursday in May, 1885. F. A. PALMER, Sec.

The Bee-keepers' Association of Hamilton and Tipton Counties, Ind., will hold its next meeting at Cicero, Hamilton Co., on Friday, Feb. 6, 1885. JNO. FRITZ, Sec. D. AMING, Pres.

THE NORTH-AMERICAN BEE-KEEPERS' ASSOCIATION. The executive committee of this association have decided to hold the next annual meeting at Detroit, Mich., on the 8th, 9th, and 10th of Dec., 1885. If there is any reason why this date is undesirable, it should at once be made known, that the committee may be governed accordingly. W. Z. HUTCHINSON, Sec. L. C. ROOT, Pres.

The Ohio bee-keepers will hold their annual convention in the agricultural rooms, State-house, Columbus, O., Feb. 17, 1885, where all subjects pertaining to apiculture will be discussed. All interested are invited. We hope that all county and district organizations will send representatives, for the purpose of making a permanent State organization. Can you make it convenient to attend, and deliver us a lecture? I hope you will not say no. C. M. KINGSBURY.

[Friend K., I am very much obliged indeed to you, but it will be impossible for me to get away from home for two weeks in succession, even if I were competent to deliver a lecture anywhere or to anybody. I expect to leave on Monday, the 23d, for New Orleans.]

THE NORTHEASTERN MICHIGAN BEE-KEEPERS' ASSOCIATION.

Will hold its third annual convention on Wednesday, Feb. 4, 1885, in the Opera Hall, at Vassar. No local society has better meetings than the N. E. Mich. President Taylor has visited New Orleans, and will probably be able to give an interesting account of the apianian department of the Exposition. Reduced hotel rates. Those going on the cars will please write for railroad certificates and secure reduced rates. W. Z. HUTCHINSON, Sec.

NOTES FOR BEE-KEEPERS WHO INTEND GOING TO THE CONVENTION AT NEW ORLEANS, FEB. 24, 25, AND 26.

The convention will assemble at 10 o'clock A. M., in the Lecture Hall on the Exposition grounds. Among the subjects that will be considered during the sessions of the convention will be reports of the honey resources and productions of America and Europe; preparation of honey for market; transportation; lower rates of freight for it; marketing; the advantages of foundation; sections; the best size and best way to use; the best race of bees for America; prevention of swarming; fertilization of queens; artificial pasturage; bee-keeping as a pursuit; besides, the discussion of other questions of interest that will be propounded during the convention.

Essays to elicit discussion are expected from some of the most prominent bee-keepers of Europe and America.

Bees and supplies to exhibit must be sent with all freight prepaid, and directed to Maj. E. A. Burke, Director-General of Exposition, for Department of Agriculture, New Orleans, La.

The Board of Management of the Exposition have established a Department of Information and Accommodation at Nos. 164 Cravier and 15 Union Streets, for the purpose of furnishing visitors with information as to suitable board and lodging-houses, or furnished rooms, with directions how to reach them. For such service no charge is made. Bee-keepers, on arrival in the city, are advised to go at once to the office of this department and make the best arrangements they can for quarters; and if they will leave their cards and address at the same place, their friends will know where to find them. Most of the visitors at the Exposition find it best and cheapest to rent rooms, and take their meals at the restaurants. Furnished rooms will cost from 75 cts. to \$1.00 per day for each person; and if board is added, the rate will be about double. We are assured that the hotels have not advanced their charges. The rates are from \$2.00 to \$3.00 per day, according to location of room, etc.

Signed by the bee-keepers issuing the call for convention. See page 858, Dec., 1884.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER.
MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, FEB. 1, 1885.

Wherefore do ye spend money for that which is not bread?
and your labor for that which satisfieth not.—Isa. 55:2.

RUSSIA BASSWOODS.

FRIEND F. L. Wright intimates in some of the bee-papers, that the extravagant claims made just now for Russia basswoods originated with the party interested in propagating the trees. May be we had better wait a little until somebody has Russia basswoods blooming in our own country, before we invest largely.

ANOTHER WEEKLY BEE-JOURNAL.

FRIENDS Scoville & Pond have started a weekly bee-journal, at a dollar a year. As they did not issue their monthly promptly, I hope they will excuse us for having a little misgiving about their being able to manipulate a weekly so as to have it come out promptly on time, for so very small a sum. It is to their credit, however, that they have given us four or five numbers, any way, on time and in good shape. We extend to them our best wishes.

BEE-KEEPERS' BADGES FOR THE EXPOSITION AT NEW ORLEANS.

We can furnish a badge with a golden bee, and the words "International Bee-keepers' Congress," plainly printed, for 10 cts. Sent by mail on receipt of price. I expect to be in Cincinnati on Monday evening, Feb. 23d, according to the instructions on page 85. I shall be at the Louisville & Nashville Railroad depot with my badge on, and all that are on hand with their badges will probably have no trouble in finding our crowd.

ICE AS WELL AS CARP.

THIS 22d day of January we are having fun cutting ice from one end of our carp-pond, furthest away from the deep places where the fishes hibernate. The blocks are almost as clear as glass, and 9½ inches thick. We made a wooden frame that goes into our refrigerator in the lunch-room, and the blocks are made so as to fit this, so a solid lump can be put in each time, thus avoiding chipping up the ice, which makes it waste badly, and saving time as well. We store the ice in an unused shed, by putting in some studding and an extra lining, and then putting in sawdust so as to have 18 inches or 2 feet between the walls, all around the ice.

CALIFORNIA MOUNTAIN SAGE.

WE are again told that our specimen of the mountain sage shown in the A B C book "ain't right." A specimen was sent us when the A B C book was first started, and from it we had made an expensive engraving. After a while friend Pryall said it wasn't correct—it wasn't mountain sage at all, but some other kind. To be sure we were right we went to the expense of more engravings, and now friend J.

P. Israel, in the January Magazine, says they "ain't right." Well, friends, I begin to feel as Dr. Franklin did when they told him his ax was ground only enough to be "speckled." He replied, "Well, on the whole I think I like a speckled ax best." When the doctors will agree for a year or two what specimen of the mountain sage is genuine, we will, if necessary, go to the expense of more engravings.

COMPLICATIONS IN BUSINESS.

SINCE writing the article in another column on this subject, I have noticed in two of our bee-journals an offer of premiums to every tenth subscriber, or something like that. This will not only result in complications, but it offers something to a small part of the subscribers that the larger part does not get. If the friends will excuse the liberty I take, I would suggest that past experience has been pretty strongly against any thing of this kind. I have watched it for many years, and especially among bee-journals have such ventures been unfortunate. Another thing, it borders closely on the lottery business. The tenth man who gets a swarm of bees, or whatever it may be, renders no sort of an equivalent for them; he is simply a lucky man, because he has drawn the prize. Any sort of an inducement to get people to subscribe, aside from the old orthodox way of getting them to invest because of the intrinsic worth of the journal itself (shown on its reading pages) sooner or later seems to have met with reverse rather than success. Paying the one who takes the journal to go around and solicit subscriptions is, of course, another thing, for that is a regular channel of business. The agent receives pay for explaining and selling goods.

PUT UP YOUR GOODS IN GOOD STYLE.

SEED catalogues, and catalogues of small-fruit plants, etc., are getting to be amazingly thick nowadays, but the number of dealers who put up things in nice shape, and do all they agree to, and a little more, is not so very large, after all. Last July my attention was attracted to a vender of cabbage plants, who said he could put them up so nicely they would go anywhere, and with the instructions sent with them they could be planted safely just as well in dry weather as when it was rainy. This latter consideration was what mainly induced me to send to him. The plants came wrapped up in an old spool-box, and said box looked as if the baby had had it for a week or two for a plaything, before it was used to mail plants. The plants were badly wilted, and I could not see that they were packed at all. If any directions were ever sent to tell how to make them grow in dry weather, I never saw them. Soon after I sent for strawberries to A. T. Cook, Clinton Hollow, Dutchess Co., N. Y., whose catalogue was noticed in a late issue. The plants came packed in a new wooden box, so pretty that it was a wonderment all around. When the box was opened, a neat slip of paper, nicely printed, gave explicit directions for putting the plants out, and the plants themselves looked so fresh and handsome that almost anybody would have gladly taken the package off my hands at cost. May be friend Cook did this because he was sending to an editor, and perhaps he knew my weakness for nice things nicely put up. Any way, if he always puts up his stuff in that way, I shall expect him to build up a great business. You can tell by sending a trial order, or sending for one of his nice little catalogues, of which we have just shipped him 10,000.

Oldroyd's National Black Ink.

These inks have been sent to over twenty States in this Canon, besides Canada, India, and Asia. Rev. Samuel G. McFarland, Superintendent of Government Schools in Siam, Asia, says he has used them a great while, and likes them better than any he has ever tried. A. I. Root, of Medina, Ohio, editor and publisher of GLEANINGS IN BEE CULTURE, says he has tested and sold thousands of bottles of Oldroyd's inks, and has sold thousands of bottles of others, but Oldroyd's excel all others as a writing ink. They are not injured by freezing, and will not corrode a pen. Black ink will stand any weather. A package in powders, sufficient for one pint of either black, blue, violet, green, or red, sent free to any part of the United States upon receipt of fifteen cents.

EIGHT PACKAGES, - - - \$1.00.

FIVE DOZEN PACKAGES, - - \$5.00.

Simply add one pint of pure rain water. If too thick at any time, reduce with water.

The blue ink and my bluing are one and the same, the pint of bluing making as much as 4 bottles.

COLUMBUS, O., JULY 3, 1884.

Wm. Oldroyd, Dear Sir:—If you only knew it, and would introduce your ink to the American public, you have a sure fortune. Without exception it is the best I ever used, and I have used and sold a great deal of it in the last forty years.

Yours truly,

HARVEY BANCROFT,
Fire Insurance Agent.

Manufactured by **WM. OLDROYD,**
Columbus, Ohio.

If more convenient, we will fill orders at above prices. A. I. ROOT.

BUCK & SWALLOW,

Manufacturers of and Dealers in
APIARIAN SUPPLIES,
AND BREEDERS OF ITALIAN QUEENS.

Send for Price List.

2816 Missouri Avenue, St. Louis, Missouri.
3-5d

SMITH'S NEW COMB-HONEY RACK.

Sample by mail, already nailed, 16 cents. Racks alone by freight, nailed, per quantity, 10c per rack. Send for circular and full price list. Address:

HEADQUARTERS IN THE SOUTH FOR THE MANUFACTURE AND SALE OF BEE-KEEPERS' SUPPLIES

The Only Steam Factory Erected in the South.

Exclusively for the Manufacture of Hives.

Frames, Sections, &c., &c.

Viallon, and Root Simplicity Hives, and the 4½x4½ all-in-one-piece Sections a specialty.

Comb Foundation made on the Root and Dunham mill, of pure wax, and worked on shares.

Extractors, Smokers, Honey - Knives, Bee-Veils, and every thing needed in the apiary.

Italian Queens and Bees. No other races in my apiary or in the neighborhood. The superiority of the queens reared in my apiary is so well established, that no commendation is required. I send out no queen that I would not have for myself; and any one receiving a defective or worthless queen from me will have it replaced. Proposals from Dealers to mail a given number weekly, solicited.

Untested Queens in April, \$1.25; in May, \$1.15; in June and after, \$1.00. Rates per dozen given on application.

TESTED QUEENS from March 1st to July 1st, \$2.50; and after, \$2.00.

SELECTED TESTED QUEENS. Reared previous season, to breed from, \$3.00. All my queens are reared from selected imported mothers of my own importation, and from selected daughters.

Early 4-Frame Nucleus. With tested queen, \$5.00. I have made a specialty of the 4-frame nucleus for the last seven years, and have sent them out to all parts of the United States and Canada without loss.

Every Nucleus I send out contains at least three pounds of bees when received and sent out in the full-size Langstroth frame. They are cheaper and more advantageous than bees by the pound. Any one wishing a list of those to whom I sent nuclei the last season can have it on application, so they can inquire what they were, etc.

Full Colonies In any quantity. Perfect satisfaction guaranteed in every instance. For more particulars, and prices, send for my Descriptive Illustrated Catalogue. Cash market price for wax.

JOB LOT OF WIRE CLOTH AT GREATLY REDUCED PRICES.

Such a brisk demand has sprung up for this, and our customers seem to be so much pleased with the goods, we have succeeded in getting another still larger lot, of one of the largest manufacturers of wire cloth in the world. Please bear in mind that the only way in which we can afford to sell it at the very low price of 1½ cts. per sq. ft. is by selling the entire remnant just as it is put up. We have now in stock the following pieces. As fast as it is sold, each piece is crossed out, and the next issue will show what remains.

Width, 8 inches.—3 rolls, containing respectively 50, 50, and 60 square feet.

Width, 10 inches.—4 rolls, containing respectively 72, 70, 65, and 75 square feet.

Width, 11 inches.—One roll, containing 80 square feet.

Width, 12 inches.—5 rolls, containing respectively, 80, 100, 90, 90, and 100 square feet.

Width, 14 inches.—1 roll, containing 116 square feet.

Width, 16 inches.—1 roll, containing 139 square feet.

Width, 20 inches.—1 roll, containing 150 square feet.

Width, 22 inches.—2 rolls, containing respectively, 250, and 180 square feet.

Width, 24 inches.—3 rolls, containing respectively, 50, 55, 72, 20, 30, 110 and 69 square feet.

Width, 25 inches.—4 rolls, containing respectively, 53, 97, 142, and 230 square feet.

Width, 36 inches.—10 rolls, containing respectively, 69, 216, 290, 210, 300, 315, 216, 65, and 201 square feet.

Width, 27 inches.—One roll, containing 23 square feet.

Width, 28 inches.—10 rolls, containing respectively, 58, 150, 116, 200, 115, 40, 230, 230, 190, and 264 square feet.

Width, 30 inches.—4 rolls, containing respectively, 110, 25, 90, and 120 square feet.

Width, 32 inches.—4 rolls, containing respectively, 150, 172, 41, and 133 square feet.

Width, 36 inches.—6 rolls, containing respectively, 160, 270, 200, 150, 130, and 120 square feet.

Width, 38 inches.—5 rolls, containing respectively, 75, 316, 300, 290, and 316 square feet.

Width, 40 inches.—5 rolls, containing respectively, 300, 275, 320, 166, and 125 square feet.

Width, 42 inches.—One roll, containing 245 square feet.

Obituary.

WE are pained to be obliged to chronicle the death of our old friend W. W. Cary. He was for years an intimate friend of L. L. Langstroth, and during Mr. L.'s visit to us he had a good deal to say of his most highly esteemed friend Mr. Cary. We learn by the *Bee-Keepers' Magazine* of Jan. 1 that he has been a bee-keeper for 52 years. He made the acquaintance of Mr. Langstroth in 1850; and when the Italian bee first made its advent to our shores, Mr. Cary was one of the most active in giving it a chance, and he has furnished nice Italian queens for perhaps as long a time as any American bee-keeper. The magazine above mentioned contains an excellent portrait of our friend Cary, together with a biographical sketch of his life. Although many may not know it, our bee-keepers' medley contains an engraving of friend Cary. While getting it up, Mr. Langstroth remarked to me that many for years have noted the resemblance between Samuel Wagner and W. W. Cary, and that a photograph of one would answer for the other. Accordingly friend Cary's photograph was given, with the above explanation, as no photograph was ever taken of Samuel Wagner. Mr. Cary's business will be carried on, and, in fact, has been for some time carried on, by his son, W. W. Cary, Jr.

DIED—In Baltimore, Md., Jan. 23, 1885, Elenora, only and beloved daughter of C. H. and Susan H. Lake, aged 12 years, 2 months, 6 days.

KIND WORDS FROM OUR CUSTOMERS.

Thanks for your kindness in waiting so patiently on me. The goods I ordered at different times were all received with the best of satisfaction, especially the bee-keeper's wheelbarrow, which has been faithfully used by myself, wife, and children.

D. N. LANBERT.

Logan, Kent Co., Mich., Oct. 27, 1884.

Please find \$2.60, for which send me the latest edition of the A B C book, and GLEANINGS for 1885. I can't think of doing without them, and keep bees and make a success of it, for I think one may lose ten times the cost of both, in trying to do without. GLEANINGS is always welcome in our home.

G. A. WILLIS.

Enfield, White Co., Ill., Dec. 15, 1884.

We subscribed for GLEANINGS last year, and like it much; but having been unfortunate with our bees, we lost our enthusiasm and did not resubscribe. Had I the time I could say much of my admiration of your way of conducting business. I will just take time to say, it reminds me of a thrifty bee-hive. To a bee-man, that expresses much of order, industry, happiness, and profit.

If you choose you can send some cards for dis-

tribution, as I am teaching in the country, and have a good many boys in charge, ages from eight to eighteen, and I think they would appreciate them.

Russ, Tex., Nov. 11, 1884. Mrs. M. TALIAFERRO.

SOME KIND WORDS, AND NO MISTAKE ABOUT IT.

The goods came all O. K. Many thanks. The carpet-sweeper, my wife thinks, is the nicest thing out, and I think "How the Farm Pays" is something that every farmer ought to have, and every young man who intends to be a farmer, or even if he doesn't ever intend to be one. He may become the owner of a farm, and with what information he would get out of that he would know at a glance what kind of seed to sow to be the most profitable, and he also may know whether his tenant is competent to conduct a farm or not, and every thing pertaining to a farm, farm implements, etc. The book has paid me already in one article on grape culture. If I am a blacksmith and a bee-keeper also, the A B C book has paid me double and tenfold for itself, just in one point of dressing saws. Sometimes I could dress a saw, and it would saw well, and the next time it would hardly saw at all, and my neighbor was about to get all of my custom. But a glance at the article in the A B C turned the scale, so I dress from 3 to 5 saws every week, where, before I got the A B C, may be I would dress one a month. Somebody else would dress it the next time. But that is not the case now.

MY REPORT ON BEES.

This season was almost too dry; spring count, 11; sold six, and increased to 22, all alive at date. Honey very dark, and strong to taste—very bitter. Honey-dew was the cause.

Every household or family ought to take GLEANINGS, for the one heading, Our Homes, Myself and my Neighbors, and, in fact, every heading in it is worth tenfold the price of GLEANINGS for one year.

Waynesburg, Pa., Jan. 15, 1885. T. A. INGRAM.

[Why, my good friend I, it seems to me you must be unusually easy to get along with, or you would not be pleased at our humble efforts in every direction, as you seem to be in the above letter. I confess I am very glad indeed to find that our publications, and the goods we furnish, have been the means of doing you so much good in your home.]

SOMETHING NEW.

As I have greatly increased my facilities for manufacturing

Apiary Supplies,

It will be to your advantage to send for price list before purchasing elsewhere. Cash paid for bees-wax.

A. B. HOWE,
Council Bluffs, Iowa.

SECOND-HAND FOUNDATION MILLS.

We have at present four mills, which we have taken toward new ones. The first one is a 5½-inch Washburn mill; price, when new, \$20 or \$30—can't just remember now; but our present price for a 6-inch mill is \$15.00. We will sell the mill for \$10.00. The second one is a 9-inch mill, such as we used to make for the L. frame. We will sell this for \$17.00. The third one is a 10-inch mill, our own make. The present list price is \$25.00. We will sell it for \$18.00. The last one is a 12-inch mill, our own make. Present price of a new 12-inch mill, \$40.00. We will sell this for \$25.00. All the above mills have been worked over so as to make the new style of cell. Samples of the work will be sent on application. We will allow 5 per cent off from prices mentioned above, for cash with order.

A. I. BOOT, MEDINA, OHIO.

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey.*—Our honey trade has been very large this year, but prices have ruled extremely low. We have tried our best to maintain prices, but the flood of California honey, both comb and extracted, and of extra fine quality at that, which has accumulated in the large markets all over the country, has compelled us to meet the competition. This has caused some dissatisfaction on the part of shippers who thought their honey should have brought more, but it is impossible to satisfy everybody. We are now short on choice 1-lb. sections, and would pay 14c per lb. for some white clover or basswood 1-lb. sections in glass front, clean new cases of not over 30 lbs. each. We could use 2000 to 5000 lbs. of it, and would pay cash on arrival.

JEROME TWICHELL, of

CLEVELAND, CLOON & CO.,

Jan. 22, 1885. Cor. 4th & Walnut St's., K. C., Mo.

ST. LOUIS.—*Honey.*—The cold weather has checked demand for honey. Comb neglected. Extracted, in barrels, Southern, worth 5½¢@6c. Northern, worth more, but slow sale. An occasional sale of 1 and 2 gallon cans at 10c. Choice white clover, 15¢@16c. in one-pound sections. Dark honey unsalable. *Beeswax* quiet at 26¢@30c. Stock small, and not much arriving.

W. T. ANDERSON & CO.,

Feb. 10, 1885. 101 N. Third St., St. Louis, Mo.

CLEVELAND.—*Honey.*—The honey market, like every other kind of merchandise, is very dull; sales during January were scarcely anything. February, so far, has been no better. Choice 1-lb. sections of white honey move slowly at 14¢@15c; 1½ and 2 lbs., 13¢@14c; second quality not wanted. Extracted in no demand. *Beeswax* scarce, 28¢@30c.

A. C. KENDEL,

Feb. 11, 1885. 115 Ontario St., Cleveland, O.

FOR SALE.—I have on hand 3 barrels of choice fall honey, which I hold at 8½c per lb. It was well ripened before extracting, and is put up in alcohol barrels.

H. W. FUNK, Bloomington, Ill.

FOR SALE.—One keg extracted clover honey, 110 lbs., for \$10.00.

HEDDON'S LETTER.

Moral Patents.

HEDDON'S HIVE, HONEY-BOARD, HONEY-PLANTS, &c.

ON first page of your last issue I find a letter from brother Hatch to brother Hutchinson, from which I gather the idea that brother Hatch thinks that our government sells a monopoly to a person when said person takes out a patent. I think he is in error. What we pay the office is record fees, and the monopoly is only a monopoly of the inventor's own discoveries; a monopoly of what he has produced by the labor of his own brain and hands; a monopoly of what did not exist before his efforts brought it into being. The office gives him the 17 years' exclusive right, charging only fees to support the recording and other office labor.

WIDTH AND SIZE OF ONE-POUND SECTIONS.

Brother Hatch also says, that in my "circular, page 20," I claim that the $4\frac{1}{4} \times 4\frac{1}{4} \times 7$ to-the-foot (or $1\frac{1}{2}$ scant) sections do not average one pound. He does not say whether he means my 1883 or 1885 circular. I can't find a word about it on page 20 of either circular. Neither can I find on any other page where I call that section a scant one-pound section, except when used with separators. Well, be that as it may, I have the fresh fact to state, that the past year we learned how to get this section so plumply filled, attached to the wood all around, that the part of our crop stored between separators, in this size section, averaged almost or quite exactly one pound per section, gross weight; that is, section and all. We can also average one pound with $1\frac{1}{2}$ -inch wide, $4\frac{1}{4} \times 4\frac{1}{4}$, when used without separa-

tors, if I recollect correctly. Regarding the system of management, I will give that at a future time.

PRICE OF CASES.

Brother Hatch says he could also furnish my cases at half my price, and make money. Has he seen my 1885 circular, where, on page 4, I quote these cases, in quantities of 26 or over, at 16c each? This includes handles and the five tin strips. I should like to buy of him at 8c each. No doubt he thinks he tells the truth. Does not much depend upon the quality of the material given? But suppose, for argument's sake, he could. Suppose he has the advantage of very cheap lumber and cheap power, and cheaper laborers. Must I, on that account, go entirely without any remuneration for my invention and introduction of this case? I infer that brother Hatch is a "Christian," and I think he should have seen these moral points sooner.

MOORE'S RACK.

This, I think, is properly named. I do not see that it is like, or fills the place of, my case. The tin strips at the bottom are not original with me. They are very old; so neither are the wood partitions. I claim them only in combination with a case that is to need no outside covering; that uses open-top sections; is bee-space taller than said sections, and adapted to the tiering-up plan (a splendid plan of manipulation), and taking the cover of the hive in the same manner that the brood-chamber does, and so arranged at the bottom as to be adjustable to the ordinary hive with bee-space above the frames, or my honey-board with bee-space in its upper side. Is brother Moore's like that? I think not. If so, it could not be made of material $2\frac{3}{4}$ inches wide, unless $2\frac{1}{4}$ -inch sections were used. I think that the difference in the popular growth between the rack

and the case is illustrative of their difference in construction. I don't think that brother Hutchinson, Cook, Sears, and a host of others, use a case or any thing else, just because I tell them to or ask them to.

HUTCHINSON'S HEDDON HONEY-BEARD.

I see you published my letter (by permission) on page 98. All right, only I don't see the clause wherein I said that brother H. did not claim the honey-board, only the queen-excluding feature. Did I put this sentence in the other part of my letter, or how? I know such to be the case; and as the letter reads, some might infer that I reflected upon brother H. in the matter, which is far from correct, as I place the highest confidence in his keenness of moral sense and vision, as well as the most sterling integrity in all his acts and speeches. Would that the world were all like brother H. Think of the comfort and economy!

Accept my thanks for your generous gift of \$100, which is thankfully received. I appreciate it, and will say I can't help but feel honored by your appreciation, after these years of toil. I am not done yet. A word about—

HONEY-PLANTS.

And I will close. I think we should avoid all plants not indigenous to our climate and soil, or readily adaptable to them. I am quite sure that *Epilobium*, or willow-herb, will not prove a success so far south as we are. I hope you will prove or disprove this statement. I can see no returns for labor, land, and seed, unless a plant is tough, generally sure of secretion, self-sustaining, and I am not sure but I may add, will thrive, spread, and increase in waste places, with only just starting. I know of no plants that combine these successful points except

MELILOT CLOVER AND PLEURISY-ROOT.

I have watched the latter closely for three years. It has never "shied" once, but every year is covered with bees all through basswood bloom, or that latter part of it which it laps on to. One great advantage that it has over melilot clover is, that it is a perennial plant. Another is, that it is a perfect success on the poorest soil. I am of the opinion that it might be made to settle the problem of reclaiming worn-out land, or land so poor that nothing else could be made to shade the ground till other fertilizers could get started. Melilot clover will back out of this poor soil. Try pleurisy-root, brother Root, and report. The plant that will grow well, and reclaim worn-out land, at the same time yielding a honey dividend, or take possession of grassy and weedy fence-corners, is what I want, and what I think I have.

JAMES HEDDON.

Dowagiac, Mich., Feb. 4, 1885.

We do not find the sentence you mention, friend H., and nothing was omitted from your communication, by mistake or otherwise. You may have put the sentence in some other letter.—In regard to the epilobium, you will see from our last issue, page 86, that it does flourish as far south as La Salle Co., Ill., and Medina Co., O., friend Green being just west of us. We will sow some of the pleurisy-root seed in the greenhouse to-day. It is noticed in GLEANINGS for Sept., 1880. Three reports are there given in regard to it. Its botanical name is *Asclepias Tuberosa*. Prof. Beal there describes it as follows:

The specimens sent are *Asclepias Tuberosa*,—But-

terfly-weed or Pleurisy-root. I have received it before as a bee plant. It is one of the milkweeds, and thrives in dry hill-sides and fields, but does not contain much milky juice. It is a very pretty plant, and is sometimes cultivated.

W. J. BEAL.

Michigan Agricultural College, Lansing, Mich.

Probably friend Hatch did not know you had advertised these cases at 16 cts. each, and very likely the Moore rack will answer his purpose; if so, he can, of course, advertise them at what price he chooses; but he would, to be sure, call them Moore's rack, instead of Heddon's.

SABBATH OBSERVANCE AND THE NEW-ORLEANS EXPOSITION.

WHAT SORT OF A STAND SHOULD A CHRISTIAN TAKE IN THE MATTER?

THE decision has been rendered, and the Sabbath-breakers have won the day! The New-Orleans Exposition is to be opened on the Sabbath, during the whole period of its continuance. Not only open, but special attractions are provided, and special privileges granted to induce a large attendance on that day. The conduct of the managers contrasts sharply with that of the directors of the Centennial, who firmly and persistently resisted the demands of the godless, to open the gates on the day of sacred rest. It is not only an outrage upon the moral sentiments of the best part of the nation, but a dethroning of Jehovah, and the consecration of his day to Mammon. This act deserves the severest rebuke from every God-fearing, Sabbath-loving citizen. The *Methodist Recorder* says:

Exhibitors who respect the Lord's day should utterly refuse to exhibit their goods on that day, or entirely withdraw from the Exposition; and religious people everywhere should decline to visit and patronize such a Sabbath-breaking institution.

Are not A. I. Root and myself included in the last sentence? Yes.

If the managers of the Exposition are determined to violate the Sabbath, religious people should with equal determination refuse in every way to countenance the desecration.

JOS. SOMERVILLE.

Brady's Bend, Pa., Feb. 4, 1885.

Friend S., I am very, very sorry to receive the above. On first reading your letter it seemed to me as if I could hardly attend a place of that kind, where no respect is paid to God's holy day; but after a little further reflection I concluded it was one of those questions that often come up, that every Christian ought to pray over before making a positive decision. I should not want to decide for others; but so far as I am concerned, I think it is my duty to go, all the same. Of course, I should not go on the grounds on Sunday, neither should I want any thing belonging to me open to inspection on the Sabbath-day. Of course, many perplexing questions come in. If the grounds and buildings are full of visitors, somebody must be there to look after the goods; and while there it would seem hardly courteous to refuse to explain things, and answer questions. It seems to me if I had any loose valuables there I would take them away Saturday night, and take them back Monday morning, if the regulations permitted it. If they did not, I would do one of two things: Withdraw all such loose valuables, or let

them remain, and take the risk of having them injured or stolen. I would not allow any possible inducement to persuade me to go on the grounds on the Sabbath-day, and take part in the proceedings. Something has been said about holding meetings on the Exposition grounds. From what experience I have had in holding meetings in similar circumstances and places, I do not believe it is advisable for any Christian to encourage them. There are plenty of comfortable churches in New Orleans, I am sure, and I feel pretty sure, too, that those who love the Lord will be found in those churches. Do not let us stay away, friends, but let us go, carrying Christ with us; and if we find customs different from our notions, let us strive to do as Paul did when he said,—

I am made all things to all men, that I might by all means save some. And this I do for the gospel's sake, that I might be partaker thereof with you. —I. COR. 9:22, 23.

WIND-BREAKS, THIEVES IN THE APIARY, AND HONEY-PRODUCING PLANTS.

FRIEND LAWSON TELLS US HOW TO KILL THE ABOVE THREE BIRDS WITH ONE STONE.

FRIEND ROOT:—In your issue of Jan. 1, 1885, in your answer to John F. Whitmore, concerning thieves in the apiary, you may well say the laborers are few, while the harvest is plenteous. We also have a promise to those who help themselves. Suppose we take this practical side of the case; that is, hedge in our apiary with something that will be a harvest for the bees twice in the year, a protection against thieves, a wind-break for the apiary, and a lasting pleasure to the owner. This is a subject of vital importance, not only to the apiarist, but to all who have inclosures to make, as this combines cheapness, strength, durability, and will be defensive against the inroads of men, stock, pigs, and rabbits, at all times. To such I would recommend the Japan quince; two varieties (*Cydonia Japonica*), scarlet flowering, and *Cydonia Japonica alba*, white flowering; also the *Pyracantha*. The two former have peculiar qualifications for the position I would assign them as a hedge. They have a rich, dark-green foliage, producing in April a profusion of flowers which keep the bees busy and happy (I have seen them in bloom as early as March, and snow lying on the ground). What could be more attractive? They are defended by innumerable thorns, which make them impenetrable against all interlopers; they thrive in all kinds of soil and locations; they will make a good defensive hedge in four or five years; bear pruning admirably, and are not subject to insect depredations, either in branch or root; and lastly, they occupy but two feet on either side of the row. Propagation of the above is similar to the *Pyracantha*, hence I will speak of them together.

The *pyracantha* is essentially a hedge-plant, which can not be said of many others, especially the Osage orange, which is, perhaps, the most familiar example to most of your readers, growing sometimes to a tree in height, with strong roots extending to either side for many feet, running so near the surface, and exhausting the soil, preventing the planting of crops to within several feet of the hedge-row. Not so with the *Pyracantha*; it requires

but two feet and a half on either side of the row; it is a beautiful evergreen, with a very rich dark-green foliage, producing, in June, snowy-white flowers, much frequented by the bees. In winter it has a profusion of red berries, making it very attractive. It is also defended by innumerable thick set thorns, making it impenetrable to all alike. Almost any kind of soil and location will suit it. Like the former spoken of, it grows rapidly, bears pruning admirably, and will be a defensive hedge in four or five years.

Propagation is effected by suckers and prunings of either hedges, cutting them up six inches in length. Have the ground spaded or plowed, and leveled off. Set a line; now strike the spade firm against it, and downward at the same stroke, deep enough to set the slips one inch below the surface. The object of this stroke is to make firm the soil against the line; set the slips six inches apart against the straight side; fill up to near the top of slips, press them in with the feet; fill up now one inch over their tops, leaving it mellow and level. This must be done not later than the middle of March. In the following fall lift them, and set them out 15 inches apart, alternating the plants as the work goes on, making it attractive all along the row, the flowering time of either being some three months apart. Prune them well in, after the fall of the leaf, so as to make them grow close and thick. The pyramidal form of training is to me the most practical, as a shower can get at the surface of every side-shoot, hence no dead limbs at the bottom.

I have been minute in detail, as the time for action is at hand, and perhaps many of your readers may have the above in their gardens or lawns as shrubs. They may go to work on them now. I have been a practical horticulturist and apiarist for some years, and have had the above hedges under my care; I would assuredly recommend them as worthy of consideration. With the help of a good gate and lock, it is what all apiarists need.

It is seldom I take the pen to write what I know, as my hand is more used to the pruning-shears; but should this effort do your readers some good, you may hear from me again. J. J. LAWSON.

Point Lookout Mt., Tenn.

Thank you, friend L. It is the men who are used to pruning-shears and such like implements, that we like to have send us articles like yours. Every apiary should have a wind-break of some kind, and we have at considerable expense planted evergreens all around ours. We did not think of the thieves nor the honey-posies when we did it. Now, while I do not much fear the thieves, I should be very glad indeed to have our evergreens bear flowers; but I did not know, until you mentioned it, that that could be managed. In regard to thieves, I believe it is seldom that they venture into an inclosure when it is surrounded by a hedge. It is a sort of uncomfortable predicament for a body to get into, and thieves are usually cowards. Who can furnish us plants for sale, and what are they worth? I have noticed the Japan quince, but I did not know before that it was a good hedge-plant. If I understand you, the quinces and evergreens are to be planted alternately. The effect, it seems to me, would be beautiful, and I do not see why it would not be just what we want—useful and ornamental.

LETTER FROM AN A B C SCHOLAR.

REVERSIBLE-FRAME DEVICE.

I SENT 20 cts. for GLEANINGS this month and next. I have received the January numbers, and have not been getting enough sleep since. They keep me reading very late at night, and then in the morning I read and shake this cold weather until the fire gets warm enough to thaw my boots, and I am convinced that I can not do without GLEANINGS, and do myself justice if I keep bees. Through the kindness of a friend I got a colony and a nucleus in 1893; but I read the ABC through twice, besides a lot of old GLEANINGS, and constructed a buzz-saw and made four Simplicity hives before I owned a bee. I caught the bee-fever from one of your old patrons. I still have the same enthusiasm that I started out with. I had one strong colony and three weak ones last spring; increased to 7, and took 140 lbs. of comb honey in your 1-lb. sections. The season was cut short by dry weather.

I started out to build up an apiary, and make it pay its own expenses for keeping. I have enough profit to run it next year. I more than doubled the money I invested. Bees are all right at present.

I will send you a reversible metal-corner frame I have been thinking about. R. F. STRAIN.

Spring Valley, O., Jan. 27, 1895.

Thanks, friend S., for your kind words. Your reversible corner is the Broers corner, mentioned in our back numbers. This makes three who have studied up exactly the same thing. Now, then, we have a great moral here. A common want has sprung up; intelligent minds have been at work at it, and after mature deliberation the wisest heads seem to center, as it were, around a certain point. In all such cases as this it is a comforting thought, that the best device will be brought out sooner or later, and these inventions are almost always like a honey-comb—the product of the united work of many individuals.

DESCRIPTION OF BOOMHOWER'S APIARY.

FOR CUT OF SAME, SEE PAGE 83.

FRIEND ROOT:—Had I thought that the picture of my apiary would have appeared so soon, I would have sent you a description of it in time to appear with the view. You have done pretty well in explaining the details, except that the picture was not taken in June. The view was taken the last of September. Only a small portion of the fertilizing hives are shown, having united the rest in full colonies for wintering. The artist has omitted a portion of a row of hives which should have been seen between the fence and the first row of hives at my right. The instrument you speak of is a frame-holder, only the artist has not got it quite right in the engraving.

I have been pretty much my own employer since I have kept bees. The past season I had some help from April until July; from July until I did all my own work. I have another apiary $2\frac{1}{2}$ miles out of the village; and as August is our main honey month, you can think how busy I must have been. I took care of both yards, and ran some on shares, 11 miles away, and did every bit of the work myself.

Some days I would visit my out yard twice a day, part of the time traveling the whole distance on foot. As an explanation why I went on foot part of the time, I will say that our minister has no horse; and when he wanted a horse to use he was at liberty to take the pony whenever he chose to have it.

My out apiary contains 85 colonies; my home apiary, 75 colonies. The product of my home yard the past season was nearly 2 tons of comb honey and about 500 queens, so you see I did not idle much time away. My home apiary has a hard coating of sawdust over its whole surface. Not a weed nor a spear of grass is allowed to grow anywhere near the hives. I have often offered the sum of 50 cts. for every spear of grass or weed that could be found within range of the bee hives. Over a ton of the comb honey from this yard was gathered from the common red clover. I sent you a sample of the honey. What do you think of it? When I purchased this place, three years ago, where the hives now stand was nothing but a thick hedge of old apple-trees and lilac, and other worthless bushes; in fact, one could not see from the window to the street; but the pick-ax and crowbar did the work pretty well, with me as their motive power. You know we are commanded to earn our bread by the sweat of our face. F. BOOMHOWER.

Gallupville, N. Y.

HEDDON'S HONEY-BOARD AND HIVE-COVER.

FURTHER PARTICULARS.

IN the cut given last month, page 85, which friend Heddon furnished, the cover is represented as a flat board, E. The friends may remember that I was a little tenacious of the opinion that such a cover would warp. When the hive came to hand, however, it transpired that the picture did not represent the cover at all. The cover friend H. sends us is shown below, at fig. 2. You will notice that, to prevent the warping I spoke of, he has put a piece of one-inch lumber, set up edgewise, on each end, and these pieces are fully as wide as the cleats around our Simplicity cover. To be sure, we can hold them from warping, if clamped in the above manner; but even if warping is prevented, the arrangement shown is not proof against twisting, and the sample hive furnished by friend H. had the cover so badly twisted when it reached us (I can not say how it was when he started it) that I would undertake to get robbers under it in less than half a day, in our apiary. Very likely such covers will work all right generally; but after four or five years of use, if they do not trouble by letting bees under during a severe dry spell, it will be contrary to all my experience. Another thing, this cover, with its great clamps on the ends, projects over the hive all around; and in shipping bees in a hive or otherwise, it would get knocked loose unless very securely nailed or screwed fast to the hive. A cover can be made on the plan of the Simplicity, just about as cheap, and I should very much prefer it; and if you can make bees push under a Simplicity cover so as to get robbing, I should like to see it done. The Simplicity cover also slips into place, and stays pretty securely. The above cover has no

place, but stays just where you lay it. Of course, all the friends can make covers as they think proper.

Fig. 1.—Slatted honey-board.

Fig. 2.—Hive-cover.

Fig. 3.—End of honey-board, showing how the slats are let in.

Figure 1 represents the slatted honey-board. The piece across the center is a piece of tin, to keep the spaces a little more accurate. The ends of the honey-board are rabbeted, so that the slats catch into the rabbet, as shown in figure 3. The honey-board is framed all around like a slate-frame, and this frame rises $\frac{1}{4}$ inch above the slats forming the bee-space. The pieces forming the sides of the frame are beveled off on the inside, so as to allow the bees to go up into the sections on the extreme outside. This honey-board, outside dimensions, is exactly the same as the top of the hive. The crate of section boxes is also the same, outside dimensions, so that hives, honey-boards, or crates of sections, can be piled up at liberty. No matter how you pile them, you always have the bee-space between them. The first bee-space is formed on the top of the hive, brood-frames coming $\frac{1}{4}$ below the outside edge of the hive. The honey-board, being flat on the under side, rests on these edges. The crate of sections is also flat on the under side; that is, the sections come down even with the lower edge of the crate; but on the top of the crate the sections are this bee-space below the outside edge of the crate.

If there is any thing more that is not fully understood in regard to Heddon's hive and system, I shall be happy to explain it.

A HINT FROM FRIEND FRADENBURG IN REGARD TO RABBITS.

AS a word of caution, I will suggest to you that, if you have not provided a suitable place for your doe rabbit to make a nest for young ones, that you do so at once, as she might be likely to have young at any time now; yet she may not before March or even April, and it would be a pity to lose the first litter for the want of a suitable nest. I have now five nests of young kids. If she is out of doors, I would suggest an old chaff hive would make an excellent nest-box, with a hole cut in one end to let the doe in and out; but whatever is fixed, the hole should be as near the ground as possible, or a banking of earth made up to the hole, for the little tads will come out sometimes, and not be able to get back, and so get chilled and die.

A. A. FRADENBURG.

Port Washington, O., Feb. 8, 1885.

Thank you, Friend F. Our bunnies shall have a nice nest made forthwith. As they adjoin the Jersey cow's stable, I think we

will put the chaff hive in the stable, with the opening into the rabbit-pen; then, you see, when the bossy is covered up with that pile of leaves, the little "tads," as you call them, will be right in the same nest with "bossy."

OUR IMPROVED CUTTER-HEAD

FOR MAKING THE ENTRANCES TO SECTION BOXES, AND OTHER PURPOSES.

WE have formerly made our cutter-heads so that a pair of spurs were used in connection with the knife. These require frequent sharpening, and there is a difficulty in getting them adjusted so as to work exactly with the knife. The engraving below shows a knife bent at each side so as to form a spur on the edge of the knife itself, without necessitating a separate spur.

MACHINE FOR SCORING PLANK SO AS TO FORM ENTRANCES FOR THE BEES IN SECTION BOXES.

The above arrangement makes the whole machine plain, without much explanation. The mandrel is 18 inches long; pulley, $3\frac{1}{2}$ -inch face, and $2\frac{1}{2}$ inches in diameter; boxes, $2\frac{1}{2}$ inches wide. The head that holds the cutters is $2\frac{1}{2} \times 3\frac{1}{2}$. By loosening the bolts on the heads, cutters for different purposes may be attached.

A REPORT PARTLY ENCOURAGING AND PARTLY-DISOURAGING.

ORDERING GLASS AND ALL WHEN YOU ORDER CRATES, ETC.

I COMMENCED with 7 last spring; increased to 15 by natural swarms, and about 200 lbs. of nice comb honey, most of which is sold at 20c. per lb. The honey was in 1-lb. sections, and went like hot cakes. The next thing to do is to get goods for another year. First, send to an honest dealer, even if he is off a good way, and the freight is high; better do that than to buy of some one you don't know, and then not get any thing. Buy every thing that goes to make one piece or one article. For an example I will state my experience.

Early last fall I wanted some goods, so I sent to you. Goods came as I ordered, on short notice. Among the rest were some shipping-cases. To save expense of breaking the glass, I said leave it out. I expected to buy here as cheap as there; but when I came to buy, the dealer told me the glass would cost me 40c. per crate; so I just took glass for one, and thought that would do until I ordered again, and so it did; but, here is the result: I put the glassless crates in a room I supposed to be tight, but I suppose there must have been a nail-hole to start; and after a start was once made, no stop. The bees were almost as thick in the room as a swarm. I opened the door and window to drive them out; but in spite of Clark's smoker, muslin, needle, hammer, tacks, nails, strips of wood, and

every thing else but glass, they got twice as much honey as the glass would have cost, besides the fun of the stings, which is legion. After this I want glass, glass, glass, for my honey-cases.

Coal Vale, Kas.

S. C. FREDERICK.

Now, friend F., let me make a suggestion. Get your price lists in winter, long before you need the goods. Study them very carefully, then go to your nearest store, and ask how they sell glass. Ask them, also, what they charge for the exact size you want. If the price named is more than the freight from the supply-dealer, then order of him; and I would suggest to supply-dealers that it may be well for them to take some lessons in packing glass. Glass can be packed so as to go safely across the United States, but it is not always done.—About the robbing rampage you had, friend F., next time you get into a scrape like that, if your windows can not be made tight otherwise, tack a sheet or table-cloth up over the window, and put strips of lath around the outside. Fix all other rooms in a similar way. Let the robbers out at night, just before dusk, and I guess it will be a pretty good idea to have each case of honey so secure that it is of itself bee-proof. Sometimes the bees have made pretty bad work on a case of honey during transportation.

HANDLING HONEY, AND PREPARING IT FOR MARKET.

SOME SENSIBLE SUGGESTIONS BY A GROCER'S CLERK.

MY "better half" is very much interested in reading GLEANINGS, for the many appropriate suggestions it contains in regard to the handling and care of bees. It is certainly of great importance, if one designs to make bee keeping a permanent business, to thoroughly understand all the little details that go to make the venture a paying one; and the season being a favorable one, and an abundant honey crop being secured, comes the last but not least item, how can the product be successfully marketed to the best advantage to both seller and buyer?

I have recently been employed in a store where a large amount of butter, honey, eggs, and various other country produce was brought in for sale by the farming community, and I know that the readiest sales were always effected by those who took extra pains to bring their packages in a neat and tasty condition. A poor quality of butter, if brought in a clean tin pail, nicely stamped and covered with a clean white cloth or napkin, would command a readier sale than a much better quality brought in a rusty pail, eight or ten pounds in a roll, jammed into a pail any way, instead of being laid in with care, not stamped, except by fingerprints, a liberal allowance of hair and straws, the whole surmounted by a brown dish-rag for a covering, or something similar. You may think this a strong assertion, but it is *solid fact*.

Our grocery department was located in the rear part of the store, and what honey we took in was there stored on shelves, mostly in two-pound sections. Of course, it dripped; and every little while a wash-basin of water and cloth were called into requisition; the shelves were a bait for the flies, and

every article brought into contact was sure to get "stuck up." Of course, the sales were slow, and oft-times required considerable argument to effect one.

I expect to have a considerable quantity of honey to market this coming season, and have made up my mind that, to create a demand for the product, it must be placed on sale in a *presentable* condition, to say the least. I purpose to make a glass showcase, of a sufficient height to hold an ample number of one and two pound sections, tiered to show off the contents to the best possible advantage. The top of the case can be used for storing up a quantity of extracted honey, either in glass jars or tin pails, the whole in summer season to be covered with mosquito-bar, to protect the labels from flies; and being placed in a convenient position for securing notice, it seems to me that such a method will command ready sales, and that honey will not go a begging.

L. S. WALKER.

Vernon Center, N. Y.

GROWLERY.

SOMEHOW this department of late has been rather laid on the shelf; and, in fact, I had almost forgotten the years in which I used to get unkind letters through the press and otherwise. The writer of the following has, at different times, attacked me publicly, and called me hypocrite, etc. As nearly as I can remember, his complaint is, that I refused to pay the return charges on a box of fdn. which I sent him, and which he wished to return, *long after the honey season was over*. I wrote him that if, on examination, we found the fdn. in our opinion not what it ought to be, we would return him the money, paying all charges both ways. If the fdn. was, in our opinion, faultless, *he* must pay the charges both ways. On receipt of it I carefully inspected it, and pronounced it fully up to the average we sent out, and therefore remitted him what he paid, less charges. May be our fdn. is not equal to some sent out by other manufacturers; and if this admission, or this letter which we give below, injures our trade in the commodity, let it be injured. Here is the letter, written to our postmaster:

Postmaster, Medina, Ohio:—

Dear Sir:—Will you please be so kind as to inform me of the whereabouts of one A. I. Root, late of your city? He owes me a little bill, and has failed to respond to my requests for a settlement. Perhaps he has left for other parts. Can you tell me where he may be addressed? I believe he has been a dealer in glucose, and advertised a 3-cent counter. Please answer on enclosed card, and oblige yours, etc.,

Feb. 9, 1885.

I am not aware that any letter received from the friend above has remained unanswered, and I can not see that it would be right for me to hand over the money in answer to any such demands. I have no ill will toward the writer, and I do not know what more I can do than to pray that God may take away his unkind, unreasonable, and bitter spirit. If I have not stated the above correctly, and he wishes to reply in a courteous manner, I am willing to give him as much space here as I have occupied.

SOME EXPERIMENTS.

MORE ABOUT PREVENTING THE CRYSTALLIZATION OF SUGAR SYRUP BY THE ADDITION OF HONEY.

ON page 13, friend Root says to J. D. Gehring, "Very good, friend G. But if honey effectually prevents crystallization, what is the use of going to the trouble of boiling it? Just pour boiling water on your sugar, put in the quantity of honey mentioned, stir it thoroughly, and there you have it, without taking it near the stove at all." But the trouble is, "there you *don't* have it," and that is often the trouble with us when we attempt to make theory take the place of practice, and scientific thought the place of fact.

When making my different experiments last fall, to see if I could not get a syrup for feeding purposes which would not crystallize, and thus bother the bees, I also tried another, which was, to see what quantity of sugar syrup must be added to honey to keep it from granulating, as I had a few people who desired honey fixed so it would remain a liquid for an indefinite time, while all know that nearly all of our honey will granulate in a few weeks after being liquefied by heat. As in these experiments the honey must still hold the same flavor afterward that it did before, of course I could not boil it, for by so doing the flavor is always changed. So I made a syrup of the consistency of honey, and let it cool until it was no warmer than that I could hold my hand on the outside of the vessel which contained it. I now took six glass dishes, and in the first I put all it would hold of the regular bee-feed, such as I told you of last fall. The second I filled with clear syrup as it came from the vessel spoken of above. For the third I took three parts of this syrup and one part of my best honey, which had not yet begun to granulate. This honey was first carefully mixed with the syrup, by putting both in a vessel together, and stirring until thoroughly incorporated, when it was poured where it was to stay. The fourth contained a mixture of one-half honey and one-half syrup, incorporated together as was the third. The fifth glass contained a mixture of three parts honey and one part syrup, while the sixth was filled with clear honey. All were now carefully secured from dust and moisture, and set away in a dark place in my shop, where they have been left unmolested for 3½ months. The mercury has been as low as 12° below zero in this shop during this time, and as high as 80° above.

To-day I got out these dishes, and this is how I find them: The first, or bee-syrup, remains exactly as it was when placed there, thus showing that I have a permanently good thing in the shape of 30 lbs. sugar, 15 lbs. of water, and 5 lbs. of honey; the water first being brought to a boil, then the sugar poured in and stirred half a minute or so, when this is allowed to boil. The honey is poured in, and the whole mixed as soon as the vessel containing the syrup is taken from the fire. I have given the process in short again, thinking you might have some new subscribers for 1885 who would not see my 1884 article.

The second, containing clear sugar syrup, has the dish one-half full of clear, transparent, and whitish crystals, while the liquid portion is nearly as thin as water.

The third (¾ honey, ¼ syrup) has a few crystals attached to the sides of the glass, while the bottom is quite thickly covered with crystals, the syrup being a little thinner than when first made.

In the fourth, which is ½ honey and ½ syrup, I find little change, except here and there a little speck of granulated honey the size of a pinhead and smaller. I can not detect a single crystal anywhere. Were it not that this takes ½ instead of 1-10 honey, it might be equally valuable as a bee-feed.

The fifth (¾ honey and ¼ syrup) is granulated into a soft pliable candy, which would do quite well for shipping queens with, if it will not soften so as to run in warm weather. It is very much whiter than the sixth (clear honey), which is granulated very hard and solid, except having a little moist look on top.

From the above it will be seen that it becomes almost a necessity to boil our bee-feed, no matter how much the "gude wife" may object, if we would have a first-class feed in every respect. Those of us who have steam-engines can boil it with steam, and by the barrel, to which the "gude wife" will not object; while those having an oil-stove will find a convenient place in almost any unoccupied room where they can prepare the feed.

G. M. DOOLITTLE.

Borodino, N. Y., Jan. 26, 1885.

Friend D., perhaps you did not mean to accuse me of attempting to make theory take the place of practice; but the close of your first paragraph looks a little that way. I think we have fed about as many tons of the sugar syrup as most of the brethren, and I believe our bees generally winter pretty well too, and we have done it without boiling the syrup either. Lately we have used a steam-pipe in a large tin can, because we can get the sugar boiling quicker that way than by pouring boiling water on it. If 30 lbs. of sugar, 15 lbs. of water, and 5 lbs. of honey behaves itself right along as it has with you, I do not see what more we desire, and we owe you a vote of thanks for the experiments you have made.

SEPARATORS FOR SECTIONS, AND HONEY-BOARDS.

ALSO SOMETHING ABOUT RECALLING THE DISCARDED HONEY-BOARD.

EDITOR GLEANINGS:—Many of us are surprised at the evidence presented before the N. W. Bee-keepers' Convention against their use. But for the first time it is admitted by Mr. Hutchinson that the whole case must be taken off at once, for to put in new ones beside those partly filled would surely cause bulging.

This was one of the points I made last summer in my letter. A remedy for that was suggested, it is true, by a number, that by crowding to one side unfinished sections, and facing new ones by those capped over—a vain remedy, for it only increases the evil when those are done. What bee-keeper would advise leaving snow-white capped sections in till new ones alongside are completed? Wouldn't they become soiled?

I know it is no light matter to question the evidence of such producers as Messrs. Heddon and Hutchinson; but repeated experiments in my racks, and in wide frames, to get honey I could crate has failed every time, even when using whole starters. I would, therefore, advise beginners to go slow.

When honey is booming, in tiering up and sometimes transposing sections, is the way to help the

bees; but using cases or racks spread over the whole of a ten-frame L. hive, we all have colonies which will do more and better work without tiering, if we can quickly take out sections as fast as they are filled, and put in others; and we are far less likely to be caught with a large number half filled at the end of the season.

By closely watching the seasons, and having a hive on scales, we can tell when to draw in and close up, and in time contract, by not replacing the sections drawn out, and using separators shoved up to one side, and covering the vacancy with a quilt.

Now as to honey-boards. Why were they discarded, and why now by many recommended? By their use were any such results ever obtained as have been since they were discarded? None reported have ever come under our notice.

To get the bees at work quickly, and to present the least impediment to their entrance to the surplus-chamber, is surely an object. The honey-board was cast aside as an impediment. There is hardly a doubt but that bridge-building and bracing combs, so annoying to the manipulator, can in a great measure be prevented by lessening the space between the sections. I have found it to greatly diminish the number of brace-combs, to bring the rack down so as to leave only $\frac{1}{4}$ inch space, above brood-combs. A friend tells me he succeeded well with strips of enameled cloth across and directly on the brood-frames. With my rack resting on a $\frac{1}{2}$ -inch strip across each end of it, I can, with a knife, loosen the rack without disturbing the brood-frames.

In manipulating we have frequent need to get into the brood chamber, and any honey-board is in the way. Did we not all think it a grand step forward when the flexible quilt was substituted for the cumbersome honey-board? J. W. PORTER, Charlottesville, Va.

MICHIGAN STATE CONVENTION.

What I Saw and Learned.—No. 4.

A BEE-CELLAR WITH A RUNNING SPRING IN IT.

J. H. ROBERTSON still succeeds nicely in wintering with his large cellar with a spring in it. He did not agree, that pollen was the cause of the dysentery among his bees. Prof. Cook suggested it was because of the stream of water that equalizes the temperature. Now, it occurs to me right here that possibly a stream of spring water running through the cellar may be as good, or better, than the sub-earth ventilator. The water would be constantly bringing heat from the body of the earth, and the stream might be spread out in its passage through, so as to yield up a great part of its heat before it goes off.

SAVING HONEY BY CELLAR WINTERING.

A number of testimonies seemed to indicate pretty decidedly that a saving of something like 10 lbs. of honey per colony was made by wintering in cellar, compared with outdoor wintering. I suggested that a good chaff hive should give almost as good results as a good cellar; but I was told by quite a number that I was mistaken. Now, I know there is a saving of honey by having bees in a good cellar; but in our State of

Ohio I can hardly think it amounts to as much as 5 lbs. per colony. This 5 lbs. of stores, at the present price of sugar, need not represent more than 25 cts.; and I do not believe we could put our colonies almost to the cellar, and take them out, including the preparation needed to make the cellar dark, well ventilated, etc., for much less than 25 cts. per colony. Besides, with the changeable weather we have here, sometimes almost a week when there is not a bit of frost right in the middle of January, most of our Ohio people are, I believe, decidedly in favor of outdoor wintering, especially late years.

I was not present at the afternoon session of the last day, and therefore I take the following from notes sent me:

Friend Hutchinson says he would prefer frames for queen-rearing not over 8 or 10 inches square. This revives the old question of a divided Langstroth frame, or a frame to hang crosswise in the Heddon Langstroth Hive.

HOW FAR APART MUST HIVES BE PLACED IN THE APIARY?

James Ure thought they should be placed about 9 feet; Dr. Mason thought 6 feet, and Dr. Whiting thought they might be as near as six inches. I think all of the gentlemen may be right; but if entrances are only 6 inches apart, there should be some strongly marked difference between the entrances. With our arrangement of the house-apiary there is no confusion, even though the entrances are but a few inches apart, because there are only three entrances on a side, while with lawn claff hives, made exactly alike in every respect, and facing the same way, there is often confusion when they are as much as 14 feet apart. Prof. Cook illustrated it in this way: His house and Prof. Carpenter's house are almost exactly alike in appearance and points of the compass. Now, although they are several rods apart, when honey was exposed on Prof. Cook's back porch, so that the bees got to robbing, they would swarm around the back porch of the other house, and I should be pretty sure they would, had he not said so. This is one considerable trouble in not making a lot of hives alike, even if they are several rods apart in a large apiary. I once before suggested that we might make use of this feature in making artificial swarms and nuclei. Nobody has worked it out yet, that I know of. A methodical bee-keeper likes to have his hives uniform; but if he does, he will be pretty sure to have bees getting into the wrong hives. Making them face to the same points of the compass helps the matter; but then we have bees wasting their time while heavily laden, trying to get in at the back side of some hive where there is not an entrance.

We copy the following paragraph from the *American Bee Journal*:

GETTING NICE HONEY.

Upon request, Miss Wilkins told how she and her sister managed to secure such nice honey. They used the Doolittle system and removed the honey as soon as sealed. They use the nicest white-poplar sections that they can procure, as they thought that this made a great difference in the appearance of the honey. The propolis is not only scraped from the sections as soon as they are taken from the

hive, but all stains caused by the propolis are carefully scraped away with glass. Another and important reason for their honey being so nice, is the source from which it is gathered; viz., the willow-herb.

From the above it would seem that the Wilkins sisters are troubled with propolis and stains from letting the bees have access to the sections, as well as we are. I tell you, friends, we don't want bees tramping over our nice white basswood sections.

VENTILATION.

Dr. Whiting recommended raising the hive from the bottom-board. This is equivalent to the plan of ventilating the Simplicity hive, and I do not believe any thing can be invented more simple than the entrance adjustment of the Simplicity hive, for accommodating the bees as they go out and in, and for giving all the ventilation that may be needed.

REPORTS ENCOURAGING.

MY REPORT FOR 1884.

I COMMENCED the spring of 1884 with 21 colonies, all blacks; increased to 57; obtained 247 lbs. comb honey from top story, about 800 lbs. in section boxes; the rest in brood-frames; ten colonies made no surplus; average weight of hives, put in cellar Nov. 23, 55 lbs. From all reports I read, I think my yield fully up to the average; but the slow sale or no sale at paying prices makes me wish I had never engaged in the business.

A WORD IN FAVOR OF THE ZINC HONEY-BOARDS.

I used the zinc honey-board on nearly all of my hives; in only two did I find the queen in upper story; almost invariably I found brood in upper story when I used wooden honey-boards. This trouble cost me more than the zinc honey-board.

BOKHARA CLOVER.

I invested 50 cts. to test the merits of this clover for all purposes recommended by different writers. I now expect to expend \$50.00 in the next two years, trying to eradicate the noxious weed from my premises. I admit that bees work upon it, but my stock refuse to touch it, with the exception of one horse.

E. E. BABCOCK.

Elroy, Wis., Jan. 22, 1885.

Friend B. Bokhara clover is not intended to be used for stock, although if cut at the proper age, they will use it to some extent. All you have to do to eradicate it is to cut it off before it goes to seed. You can very quickly wind it up by this treatment. If you try to dig up the plants, no doubt you will find it a tough job.

A TRUE REPORT.

I started out last spring with 47 swarms, partly Italians, partly blacks, and partly hybrids. They increased to 103 swarms. I received 800 lbs. of comb and 400 lbs. of extracted honey. The latter was sold as fast as I could extract it, at 10 cents per lb. The comb honey I have still on hand, except about 300 lbs., which I sold at 15 cents per lb. This makes my income for the season \$85.00. My expenses for the running year were, for hives, sections, comb foundation, extractor, shipping-cases, etc., \$274.98. My report is true. I sold all of my bees last fall, but 75 swarms, and I want to sell about 40 or 50 swarms

more. I will try it with the rest once more, and run for extracted honey only, as it sells the best here. If I do not make enough another season to cover my expenses and labor, I shall quit the business.

Dundas, Wis., Jan. 28, 1885. G. W. ALBRECHT.

FROM 21 TO 47, AND 123 LBS. OF HONEY.

Spring count, 21 colonies; increased by natural and artificial swarming to 47 strong colonies. I got 1500 lbs. of extracted and 223 lbs. of comb honey. I sold all of my honey at 10 and 15 cts., right at home. I think I could have sold 2000 lbs. more, if I had had it, up to date. I got 4 colonies from a farmer near by, who was going to brimstone them, but I went to him and turned them out, and took them home, and gave each colony 30 lbs. of good sealed basswood and clover honey, and I have 43 combs of good sealed honey left for spring feeding. I have 8 colonies on their summer stands, 24 in bee-house, 19 in clamp.

WILLIAM SEITZ.

Hustisford, Wis., Dec. 22, 1884.

FROM A BEGINNER WHO STARTED LAST SPRING.

I bought one box hive at \$7.00; and a Jones hive with bees at \$7.00; got no honey from box hive, but I got 3 swarms put in the Jones hives. Sold 3 swarms for \$6.75; got one swarm from the colony in Jones hive, and made one in Sept., just for practice, and it did well. I fed it right along, and the queen laid up to October 12th, and went into winter strong, packed all in one big box filled with chaff. They are all in good shape up to date. I extracted 375 lbs. of honey—good honey at that. I got about 10 lbs. of wax; paid \$7.00 for extractor, \$1.00 for smoker, and 30 cts. for veil. I made my own capping-knife, as I am a blacksmith. I sold my honey at 15 cts. per lb. The most money made by any colony for one week was 45 lbs. I had a big time getting my experience with them, as they treated me very indifferently at times; but as I got to understand the nature of them I got along better, and by studying GLEANINGS it brought me out all right. I have a good situation, right in a valley, where basswood is plentiful. Now, is this a fair average for a beginner? The bees I now have are worth \$50.00.

DUNCAN PEER.

Zimmerman, Can., Jan. 22, 1885.

FROM 12 COLONIES TO 24, AND \$30 LBS. OF HONEY.

I have seen no report from this vicinity (friend Pond is the nearest), so I will send in a short one. I started last spring with 12 colonies, most of them not very strong. Our best honey season is usually during fruit-bloom, and the trouble is to get colonies strong enough to take advantage of it. Last year my bees gathered but just about enough to pay expenses and winter themselves, and this year, up to Sept. 1, I thought this season was to be a repetition of last, as I had taken only 150 lbs., and hardly any honey in the hives. But as friend Pond says, I never saw brood-rearing kept up to such an extent, and my 12 colonies more than doubled, without much effort on my part.

The first 10 or 12 days of Sept. were the hottest of the season, with warm nights, and every thing seemed to be favorable for the secretion of honey. Goldenrod and asters were in their prime, and in about ten days over 600 lbs. of honey flowed through my hives, and by way of the extractor into my honey-room, making quite a different report from what I expected. I got 20 cts. per single lb., 16½ cts. per lb. in 6-lb. lots or more; I sell none for less than

that. I get granulated sugar for wintering, at 6½ cts. per lb. I have taken in all 830 lbs. honey, nearly all extracted (I feed sugar entirely for wintering). Reckoning the honey at 16½c., and six colonies increase, which are not sold, at \$30.00 (I sold 8 colonies during the summer and fall), I have cleared just about \$200, after paying all expenses, and feeding for winter. I think this is doing pretty well for this section, where we have no clover or basswood. I work in a store, and have been out but very little, and did nearly all the work myself; but you may believe I have not had much spare time for any thing else.

R. J. FOX.

Natick, Mass., Oct. 20, 1884.

25 LBS. PER COLONY, FROM 39 COLONIES.

Honey crop poor; about 25 lbs. per colony; 39 colonies, spring count; had to drop 4 colonies on account of being cramped. S. D. RUTHERFORD.

Kearneysville, W. Va., Dec. 16, 1884.

FROM 15 TO 42, AND 11 BBS. OF HONEY.

I started last season with 15 swarms and ran them up to 42, and 10 swarms came out and left without settling. I got 11 bbs. of honey last season. I borrowed an extractor.

R. S. NELSON.

New Smyrna, Fla., Dec. 4, 1884.

FROM 15 TO 17, AND 700 LBS. OF HONEY.

I had 15 colonies this spring; got 700 lbs. of comb honey, and two swarms; they are all on their summer stands this winter. They are all living yet. I love to read GLEANINGS.

L. J. HARTONG.

Inland, Ohio, Dec. 26, 1884.

BEES AND STRAWBERRIES.

I have four hives of bees on their summer stands; they had a fly the other day; they seemed all right. I have out about 2000 strawberry plants. I set them out the 3d day of last July. They looked finely when I covered them up in the fall.

Anderson, Ind., Jan. 6, 1885.

G. W. BROWN.

We clip the following from the *Watchman*, published at Union, Monroe Co., W. Va.:

LARGE YIELD.—Mr. A. Y. Leach, of Wolf-Creek District, is skilled in the management of bees. During the past season, from thirteen hives of Italian bees he extracted *twelve hundred and twenty lbs.* of honey. He uses the "Simplicity" hive, some 1½, some 2, and some 3 stories in size. The 3-story hives yielded 230 lbs., equivalent to twenty gallons. Who can beat this yield?

FROM 125 TO 400, AND 785 GALLONS OF EXTRACTED AND 1500 LBS. OF COMB HONEY.

I commenced in spring with 125 colonies of bees, mostly Italians and Cyprians, and two hives of Holy-Lands; got fifteen 52-gallon barrels of honey, and increased to 400 hives, all in good condition for winter; also got 1500 lbs. of comb honey in one-pound sections.

E. STAHL, JR.

Kenner, La., Dec., 5, 1884.

500 LBS. OF HONEY FROM A SINGLE COLONY IN A SINGLE SEASON.

Bees boomed in one hive in July and August. In July one colony gave 500 lbs. of honey. How is this for a poor season?

R. JOHNSON.

Plaquemine, La.

Friend J., we are very glad indeed to get such a report from Louisiana; but your statement is so brief it hardly satisfies us. Can't you give us a little more of the particulars—what the honey came from, etc.? Was it one colony and increase, or did you so manage there was no increase?

FROM 54 TO 69, AND 4000 LBS. OF HONEY.

I commenced the season of 1884 with 54 colonies, and increased to 69, and have taken 4000 lbs. of comb honey. It wasn't a very good season here.

Bravo, Mich., Jan. 20, 1885.

D. B. LINDSEY.

FROM 6 TO 20, AND 300 LBS. OF HONEY.

Our bees have done well here in the Sioux Valley. We have increased from 6 to 20, and stored nearly 300 lbs. of honey, which we sold for 20 cts. per lb., and they went into winter quarters with about 50 lbs. of honey each.

G. L. HUBBARD.

Fairview, Dak.

2800 LBS. OF COMB HONEY FROM 30 COLONIES, AND NO INCREASE.

I keep 30 stocks of bees; and by keeping the wings of queens clipped, and running the swarms back into the old hive, or into a weaker colony, I have managed to keep to that number. I took 2800 lbs. comb honey the past year, and got \$12.00 per hive, after paying expenses.

S. R. NEAVE.

Hughesville, Md., Jan. 16, 1885.

FROM 15 TO 27, AND 1650 LBS. OF HONEY.

I am highly pleased with one year's experience in bee-keeping here, and intend to read up and carry on the trade with more system hereafter. Bees are actually getting some honey now. I have none of the winter troubles you have north. One year's harvest from 15 stands is 1650 lbs. honey, and 27 new stands.

FRANCIS TRUEBLOOD.

Archer, Florida, Jan. 16, 1885.

FROM 2 TO 10, AND 150 LBS. OF HONEY.

Well, I started with *two* colonies in the spring, weak at that, but I fed some sugar, and increased to ten by natural and artificial swarming. And I got 150 lbs. of comb honey; being a green hand at the business I could not have done so well had it not been for your A B C and GLEANINGS. If this does not go to the waste-basket, you may hear from me again.

P. L. ANDERSON.

Greenfield, Iowa.

A GOOD REPORT FROM AN OLD FRIEND.

As reports are in order, and as I have not sent you one in a good many years (and, if I remember correctly, that was a very poor one, one that would have made good material for *Blasted Hopes*); but, however, I lived through it all, and since then have been having better luck. This report is intended to cover the four past seasons. The spring of 1881 (after one of the hardest winters on bees I ever knew) found me in possession of two rather poor swarms of bees. To say that I felt blue does not express it; but I went to work with a will, and at the close of the season I had 10 good swarms and 500 lbs. of extracted honey; wintered them all successfully, and in the spring bought two more swarms, so I began the season of 1882 with 12 swarms; increased them to 31, and got 1500 lbs. of comb honey; lost five during the next winter, so I began the season of 1883 with 26 swarms; increased them to 54 swarms, and got 2200 lbs. of comb honey; lost four the next winter, so I began the season of 1884 with 50 swarms; increased them to 94 swarms, and got 4800 lbs. comb honey. You will see, by taking the spring count for the four seasons, the average per swarm is just 100 lbs., and during this time I never have bought any thing to feed my bees, they having gathered their own living.

Eureka, Wis., Jan. 22, 1885.

W. H. TENANT.

FROM 80 TO 136, AND 400 LBS. OF HONEY.

I have had good luck with my bees this year. I wintered 80 stocks; put 137 into the cellar Nov. 15; sold about 4000 lbs. extracted honey for 10 cts. per lb. This has been a very good season with us in this county.

DR. GEORGE DUNCAN.

Embro, Canada, Dec. 18, 1884.

FROM 25 TO 30, AND 1540 LBS. OF HONEY.

My honey report for the season is as follows: 1540 lbs.; 700 extracted, the rest comb. I had a good fall yield; had 10 swarms in August; one on the 2d of September. I put them all back, as I do not wish for increase. I had 25 swarms, spring count; lost none in wintering; gone into winter quarters with 30 swarms, all in good condition. J. D. HUTCHINSON.

Windsor, N. J., Dec. 19, 1884.

FROM 17 TO 35, AND 700 LBS. OF HONEY.

Two years ago last spring (April) I took four colonies. That year I had an increase of five; wintered well. The season following, my colonies numbered 22, of which I sold five, wintered 17. Now I have 35 colonies—perfect success. Notwithstanding the frost on the 31st of May, and the blight of flowers, I drew over 700 lbs. of pure honey. I have not learned to feed as yet. How many colonies must one need, to afford a foundation machine?

Killbuck, N. Y., Jan. 23, 1885.

M. E. FOLTS.

Friend F., your last question would depend somewhat on the price of wax in your vicinity, and whether you work for extracted or comb honey. At a rough guess, I should say it would pay a man to have a fdm. mill when he reaches as many as 50 colonies, providing, of course, that he has leisure time in the winter, or during stormy days, to work up his wax.

FROM 20 TO 60, AND 200 LBS. OF HONEY.

I began with 20 stands, spring count, and but 6 strong ones. My bees died off in the spring with the "dwindles." I increased to 60 good full colonies in July. I tried my new Novice extractor, and found it to be very satisfactory. I got about 200 lbs. of honey, dark, but well tasted; did not get any section honey, hence my bees are in debt to me by \$156.00. The flow of honey was limited all the season. I sold several queens, and some of them could not be bought for \$5.00 now. My bees are all on summer stands on wide L. frames, and plenty of good goldenrod honey to eat.

REVIVING FROZEN BEES.

They had a nice fly yesterday, and the snow was all over the ground, and several bees perished in the snow. Last evening I picked up about 30, which were frozen stiff, and they nearly all revived. I have them in a cage. I went out early this morning, and with my penknife cut several bees out of the ice, and brought them in, and five out of twenty revived and are in the cage doing well, after having been frozen in the ice for 14 hours or longer.

My extractor has never thrown any honey out over the top yet.

I expect to run for queens this season, as I have several orders for queens and nuclei hives, to be filled the first of March.

H. J. HANCOCK.

Siloam Springs, Ark., Jan. 28, 1885.

Friend H., the bees that fall on the ice will come to life if they are warmed up before they have been there more than from 24 to 48 hours; but after that length of time I think you will find they can not be revived,

nor can they be revived after being thus exposed to a temperature of more than somewhere about 10 degrees below zero. Perhaps I have not got the number of hours and the number of degrees exactly right, but it is something near it. Perhaps somebody else can put the figures a little more definitely.

REPORTS DISCOURAGING.

FROM 3 TO 8, NO HONEY, LOST 4 BY MOTH, AND 2 BY MICE.

YOU say that all interested in bees should send in a report, good or bad. My report is as follows: Started in spring, 1884, with 3 colonies; increased to 8, with no honey, scarcely, and plenty of moth to fight; and with all the care I could give I lost 4 by the moth, as I think, 2 by mice, and 2 I don't know how. Right here I should be glad to have some light, for last season was a peculiar one among bees here. One friend lost 19 out of 23; one lost 15 out of 16, and so on all through this section. I am under the impression that the queens got destroyed in some way or other. In all of mine I don't think there was as much "bee-bread," as it is generally called, as would fill one side of a frame full of comb. If nothing happens, I will start with Italians in the spring. You can put me in Blasted Hopes for the present; have never had occasion to use my extractor that I got of you early last season.

JAS. A. STAFF.

Moscow Mills, Mo., Jan., 1885.

Friend S., Italians would have been a great deal better to battle with the moth; but I think had you given them proper care, even the common bees would have held their own. The entrances to your hives should be so small that mice can not get in. I think a little more experience will enable you to come out all right, and I hardly think the scarcity of pollen had any thing to do with it. Queens often disappear during a severe dearth of honey. The remedy here would be to feed, and I am inclined to think proper feeding would have saved your whole eight colonies in your warm climate.

THE SIMPLICITY HIVE,

AND THE DESTROYABLENESS OF AN E-FRAME SIMPLICITY HIVE, ETC.

I HAVE used the Simplicity hive for the last five years. Before that I had used two kinds of patented frame hives, K. P. Kidder's and W. H. Lee's. I had also used three kinds of unpatented hives, the straw, the box, and the tub, the latter being made by sawing a hollow basswood log into convenient lengths, and nailing a piece of board over one of the ends of each.

The Simplicity is the best hive that I have any knowledge of, and may be the best in the world; but I do not consider it perfect. I think it would be better if it were smaller. Its length or depth could not be changed without changing the size of the frame, but it could be made narrower, and would then be large enough for any common swarm. An uncommon swarm could be given an extra top story. The advantages that would be gained would be reduced cost, increased warmth, and more surplus in upper stories. The only objection that I

can see is the fact that there are several hundred thousand of the ten-frame hives now in use, and more being made every day, and these are too valuable to be discarded. I am sure that I don't want to make kindling-wood of mine, or cut them down to a smaller size, and I will not advise others to do what I would not do myself. J. W. HARKNESS.

Keeseeville, N. Y., Jan. 24, 1885.

Friend H., this matter of an 8-frame hive has been discussed and dropped a great many times in years past. While we use 8 Simplicity sections in a wide frame, it is quite desirable to have the hive large enough to get a frame of sections outside of the brood-nest on each side of the hive. If we are going to get all of our honey built in crates, however, and not make use of side storing at all, an 8-frame hive might do very well. As wide boards for covers are quite expensive, there is quite a saving in having a narrow hive, because we can then get boards for covers without much trouble, and with not nearly as much danger of checking through the middle. An 8-frame hive is also easier to handle, and, of course, better for shipment; and where you are selling bees at so much per colony, of course it is an advantage to the producer to have a narrow hive, like small barrels for apples, and hens that lay small eggs. If the purchaser is satisfied with a colony that covers only eight combs, why, of course it is all right, and eight combs make a very fair colony. We have got to face the difficulty you mention, however—8-frame hives can not be used interchangeably with 10-frame hives. Adam Grimm has always used an 8-frame hive, and friend Heddon, as you will see by another column, has also followed friend Grimm.

WOMEN FOR PRESIDENTS OF BEE-KEEPERS' CONVENTIONS.

SOMETHING IN REGARD TO THE INDIANA STATE BEE-KEEPERS' SOCIETY.

MRS. C. Robbins, the late president of the Indiana State Bee-keepers' Society, was aware that, if the same persons attended yearly, and related their *modus operandi* of running an apiary, it would grow monotonous after awhile, and all interest would be lost, and eventually the society would become extinct. Local societies should take the hint, and every year introduce some new feature, or persons, to their reunions. The weather was very inclement, being 20 degrees below zero on the morning of the first session, yet there was a goodly number present.

It would be well if other States would imitate Indiana, and have a bee-keepers' meeting in rotation with other State societies, the bee-keepers' following the cane-growers', to be held at the capitol of the State. Scientists are attracted hither by more meetings than one, and many can have the benefit of their researches. In this way the Indiana society had the benefit of a learned essay from Prof. Wiley, of Washington, D. C., on the "Chemistry of Honey," and the result of ten analyses of honey purchased in the open market. Mrs. Robbins invited a professor from Purdue University to be present; as he could not comply, he sent a student who gave an interesting talk, with fine illustrations of the sting of bees. He also brought a powerful microscope,

with specimens of stings, from worker and queen-bees, which all so disposed could examine, which was a rare treat, as few bee-keepers ever have such a privilege.

Mrs. Robbins was the first president of a bee-convention, or of any other society where the other sex are in the majority. She was diffident as a presiding officer, but made an excellent address, and worked diligently during the year, to make the bee-keepers' reunion a success. Her hospitality will long be remembered by those who gathered in her sunny parlors and sat around her table, and her liberality whenever their eye rests upon the beautiful badges, which are unprecedented in color and finish.

MRS. L. HARRISON.

Peoria, Ill.

MAKING A PEPPER-BOX FEEDER INTO AN ENTRANCE-FEEDER.

FRIEND NELSON'S WAY OF DOING IT.

I SEND you by this mail one of my feeders. I call it the "Pepper-box entrance-feeder." I make them in two forms, square and oblong, the oblong to cover as much or as little of the entrance as you think best. The nails are for a horseradish-bottle to rest on if you want to feed more than a pepper-box will hold. I got the pepper-box feeder from A B C, and used it resting on a lath at the entrance. If from some cause the bees did not take all the feed it would start robbing in the morning, so I hit upon this device. It is very easily made, and very handy. If you object to the nails, you might run two pieces of wire through; and if it will be of any use to you, you are welcome to it. It can be used inside of the hive, as some prefer that way of feeding. WALTER H. NELSON.

New Bedford, Mass., Jan. 8, 1885.

The adjoining cut shows of itself the way in which an entrance-feeder can be made of a fruit-jar, pepper-box, or even a horseradish-bottle, as friend N. puts it. For a horseradish-bottle, you cut a piece of wood about 2½ in. square. Bore a hole in it 1½ inches in diameter, and on one side split out the wood 1½ inches.

To keep the bottle from slipping clear down in the cut. Place the open space facing the entrance of your hive, and close up against it. If the colony is weak, the entrance of the hive should be contracted pretty well, then no outside bees can push in and get around inside the feeder. You can tie a piece of coarse cloth over the mouth of the bottle, or you can have a tin cap to slip over, if you choose. The pepper-boxes that we buy at the stores, full of pepper, have many of them a perforated cover. Just set this cover so the perforations will come all into the hole, and it is all right. If you want to use a fruit-jar, of course you will have to have a larger block. Friend J. W. Utter, of Amity, N. Y., sent us a block almost exactly like the above, some time ago.

BLOCK TO HOLD THE PEPPER-BOX FEEDER, BEFORE THE ENTRANCE OF A HIVE.

He that is faithful in that which is least, is faithful also in much.—LUKE 16: 10.

MYSELF AND MY NEIGHBORS.

The tares are the children of the wicked one; the enemy that sowed them is the devil. MATT. 13: 38, 39.

I WONDER how many of the little friends know any thing about foul brood. A good many people say it can not be cured—that the only way to get rid of it is to burn up the bees, hives, honey, and every thing. That is an awful severe way to cure disease, is it not, little friends? Well, our friends D. A. Jones, and Mr. Muth, of Cincinnati, both say it can be cured; and a Mr. Cheshire, across the ocean, thinks he has a remedy for curing the bees by just feeding some of it in honey. They call it phenol. It will be tested thoroughly this season. Do some of you ask where foul brood comes from? Well, I think it comes about the way Topsy, in Uncle Tom's Cabin, thought about herself. She said she "spected that she growed;" and I guess that foul brood just grows. Now, then, does it grow out of "nothing," as some folks put it? If I am correctly informed, there is not any thing that grows out of nothing. There are always seeds hidden away somewhere. Seeds have a trick of lying dormant a long while; and then when every thing is just right, they up and grow, as if they had only just thought of it, or took a notion to grow. Alsike clover sometimes lies in the soil several years. A good many of the friends have sown figwort and spider-plant seed, and they said not a seed came up. The following spring, however, or may be longer afterward, the plants came up thickly. If you ask any old farmer if corn ever comes up

where none is planted, he will laugh at you, and say, "Why, to be sure, not, sonny. There was never a stalk of corn grew since the world was made, unless a grain of corn got planted there some way." Perhaps this same old farmer will gravely inform you that weeds grow without seeds. He may tell you that fireweeds, the kind that bear honey, start up where brush-heaps and log-heaps have been burned, and where there could not have been any seed; for if there was any seed in the ground, the hot fire would surely have killed it all. Well, now, with all due deference to old farmers, and I know they are wise and sharp in their own line of business, I think it is pretty well settled that they are mistaken. No weed ever grows without a seed, but the seed may be a thousand years old.

How many of you little friends, and I guess I will say old ones too, have not, some time or other, thought to yourself, "What makes me feel so ugly this morning?" or, "What does possess me, that such wicked and bad thoughts should come into my head, as if some imp of Satan had whispered them in my ear?" I once heard a good woman say, who was a church-member, that sometimes awful blasphemous words would come into her mind, as if somebody had whispered them. Where do they come from? In the Pilgrim's Progress, which many of our little folks have read, Christian, as he walked along one day, was startled by awful foul, wicked words that came into his mind so vividly that it seemed as though he spoke with himself; and this was just after he left the palace Beautiful. He was after-

ward told that an evil spirit whispered these words in his ear. Well, now, dear friends, although it is an evil spirit that whispers these things in your ears and mind, it is, in another sense, simply a growth of bad seeds that have been planted. They may have been planted years before, in childhood, but they were planted at some time or other, or no such crop of foul, loathsome, and disgusting weeds would ever have intruded themselves where they were not wanted. This woman I spoke of had, at some time or other, heard wicked men or boys swear, or she would not have known what blasphemous words are. Now, if you allow yourself to stay around, or to work where swearing and obscenity go on, you will find, sooner or later, that bad seeds have been planted, and they will spring up when you least expect it. Bad examples of every kind are bad seeds; and whenever we discover that bad seeds are being sown in our minds, or in the minds of our children, we should stop it at once. If Canada thistles were commencing to go to seed across the road from your corn-field, you would, if wise, pitch right into them, cut them down, and burn them up before the mischief went further.

On another page I have told you how Huber's little mind caught up and saved impressions. These impressions are seeds; and if we want our children to grow up pure minded, we want to keep them away from bad talk, bad examples, and every thing that will sow foul seeds to torment and make them unhappy in after life. Peter Henderson, the great market gardener, says the way to fight against weeds is to begin when they are so little that a light, fine-toothed rake will tear them all to bits. A man with such a rake, starting out when the weeds are very small, will accomplish more than ten men with great stout hoes could do when the weeds get to be knee high; and so it is in this work of reclaiming our nation from crime and vice. Stop the sowing of bad seed in the minds of our little ones while they are yet small, and great crops of crime will be stopped. In the same way we should work in our own hearts when spiteful feelings come up. When a disposition to dwell on the faults of our neighbors first begins to manifest itself, with the fine-toothed rake of love and charity, stop the conversation in the outset; break up all these subtle weeds that are getting a start, and let healthy plants, in the shape of good words and encouraging talk, take their place. Do not talk about people in any way that would foster or encourage this terrible evil of unkind criticism and fault-finding. Stop sowing bad seeds, and put good seeds in their place. An hour's work now may save from the penitentiary, prison, and poor-house, a dozen lives fifty years hence. Somebody once asked how early a child's education should commence, and the reply was, "Fifty years before he is born." There is a great truth here, even though the remark may provoke a smile at first thought. You can commence now sowing good seeds, and preparing the soil, or the world, as it were, for the children that shall be born in 1935; and if you do not do it now, who will

do it? The prayer our Savior gave us included this sentence: "Thy kingdom come; thy will be done on earth as it is in heaven," and every earnest, honest Christian, should bear in mind that a part of this work and this promise is to be fulfilled by our united efforts. Shall we labor for it?

Do you want to know what all this has to do with myself and my neighbors? Well, these wrong thoughts and feelings I have been speaking of are, I am sad to say, sometimes neighbors of mine. They do not live across the way, nor up stairs nor down. They are right in my own heart. I was talking with my wife about it a few days ago, and she said she guessed I was right about it; they were the result of bad, impure seeds sown in my early life, during those years when I did not profess to be a Christian, and turned my back, as it were, on Jesus the Savior. They will probably continue to sprout and start to grow in my heart as long as life shall last; but I am determined they shall be raked to pieces and destroyed, just as soon as they show their ugly heads. Those who know do say, that by years of toil you can kill pretty much all weed-seeds in your garden; and by God's help I mean to see if I can not kill, to a great degree, every seed that I allowed the enemy to sow in those early years of my life.

THE OLD MAN'S BEE-STORY.

Good Cinthy was tending the cradle,
And I in the field with my boys;
We suddenly heard the horn blowing,
And strange unaccountable noise.

I hastily turned my steps homeward,
And saw, with my wondering eyes,
Black clouds in the wildest commotion
All around our dwelling arise.

I found that my bee-bench had tumbled,
The bees were intensely enraged,
And singing and darting and stinging,
In general warfare engaged.

The pigs all around me were squealing,
And switching and running apace;
The puppies were bitterly howling,
Calves bellowing over the place.

All over my head the bees 'lighted,
And made my condition most dire;
And clawing I called out, "O Cinthy!
Please bring me some rags and some fire."

The windows were fastened securely,
My baby was screaming for ease,
"Don't open the door!" shouted Cinthy,
"The babe will be killed by the bees."

I seized an old pan, and got fire;
The ranks of the warriors I broke,
And settled the horrible conflict
By raising a volume of smoke.

My poor bees by hundreds were missing;
But when all my hiving was done,
And platform made steady, my number
Of hives was the same—lacking one.

I got all my tubs and my buckets,
And filled them with honey and comb,
And now what good lesson, dear children,
Can we from this story take home?

Whenever you contemplate building,
What'er it may be, do it well;
Be sure to have solid foundation,
Not like my poor fabric that fell.

Dear children, you're building and building—
Oh build up a character grand!
And let not your hopes for the future
Be like the house built on the sand.

Columbus, Miss.

MRS. M. A. TAPLEY.

HOW TO MANAGE

So as to Have the Hives Full of Bees When
Fruit-blossoms Come.

CONTRIBUTED BY A LITTLE BOY 9 YEARS OLD.

My brother and myself have three colonies of bees. I will tell you how we manage ours to have them full of bees when the blossoms and flowers are all ready for them to gather honey from. We take tin pans, such as mother has to bake pies in, and put some rye flour and oatmeal in them, and then put them in front of the hive, and string a little honey or sugar syrup from the entrance to the pan, and put a small spoonful of honey or syrup in front of each hive, and when they get eight or ten bees on the flour we carry them away and put them on a post or any place we can find. Then we take some sugar syrup and put it in a tumbler, place two thicknesses of thin muslin over the top of them, and turn them upside down on the frames. This we commence to do now, or as soon as the bees begin to fly, and keep it up until they can get natural flowers to work on. If this is worth a book, send me Giant-killer.

GEORGE KINGSBURY, age 9.

Mt. Vernon, Ohio, Jan. 28, 1885.

Well, now, I tell you, George, that is pretty well told. Many of the veterans may profit by the instruction you give: and there are few of us who could tell just how to do it, better than you have done. By the way, I do not know of any prettier sight for young and old than bees working on rye meal, or bits of finely ground oatmeal, in the spring. There is not a bit of difficulty in getting them at it whenever the weather is warm enough for them to fly. Feeding should be done out of the wind as much as possible; and, by the way, the bees ought to be out of the wind themselves. I have just been thinking of making a sort of cave in a side-hill, with glass sash in front, but arranged so the bees can go out if they want to, and then every sunshiny day we will have them work on meal placed not very far from their hives, in the sun but out of the wind, and out of all danger of wind and snow. With the present low prices of sugar, it is my opinion that by such an arrangement we can raise bees a great deal cheaper than to buy them when we want an increase of stock. Plenty of sugar syrup, and rye and oat meal, will set brood booming. This cave in the south side of a hill or bank, it seems to me, could be easily arranged so that the hive might stand where it won't freeze after March 1st, say. Down by the carp-pond we have quite a steep bank fronting the south, and it is quite a warm place there for the children to play, when it is windy and cold almost everywhere else. The place is a kind of hollow between two banks, so that it gets all the sunshine, and but little or none of the wind; and a roof over it, so arranged as to let in all the sun, would keep off all the rain and most of the snow, and still allow the bees to fly as far as they want to go. May be it will be a nice place for chickens as well as bees—who knows? and if the bees and chickens enjoy it, I guess likely Huber and Caddie and Constance will find it a pleasant place. Of course, we want to keep the chickens by

themselves, so that our plans do not conflict with each other.

You see, George, your little letter has just woke me up to the importance of getting our bees at work early; and why can't we set the bees at work early, as well as chickens and garden stuff? Some writer has said that he would not wonder if as much honey were yielded by fruit-blossoms as by basswood, if colonies were as strong and as full of young bees as they are in basswood time. In the years that GLEANINGS has been going, we have had several reports of protected places for bees under a side-hill. Now, then, who will work it out first? With the skill and knowledge we have acquired by this time, I do not think there need be much danger of spring dwindling. Of course, we will try a few colonies to commence with, until we are sure it is working nicely. We send you a book, George, and place half a dollar to your credit, which you can have in money, or trade out, as you desire.

GUNS.

MRS. CHADDOCK'S EXPERIENCE WITH FIREARMS.

I USED to think that if any thing would make me religious it would be to have a boy around with a gun; but I ran a gun brigade for ten years, and am still alive, and I don't feel so timid of them now. Mr. Chaddock's three brothers used to be here, and they all had guns, and were always shooting them off "promiscuous" like.

One day one of the boys sat on the porch and cleaned his gun till it went off, and the whole load of buckshot came in through an open door and passed over the dinner-table—where we had been washing dishes not five minutes before—and went clear through the outside door. Then one of them fired the gun off in the bedroom downstairs, and the marks are there yet; another of them let his gun go off in the sitting-room, and the floor carries its mark. I do declare, when I would think of it it seemed like living in a fort, with the enemy bombarding me all the time. I never felt safe. Then they all began to marry off, and go to Kansas, and they bought a revolver apiece, and they sat around the fire and loaded and reloaded them; picked them to pieces, and wiped them out, and every now and then they let one go off accidentally; and the one that went off was always the one that was *not* loaded. Then they shot at marks, to get their hands in. They fully expected to be robbed when they got to Kansas, and they wanted to be able to shoot the robber. They had pieces of paper stuck on the woodhouse, the ash-hopper, and the big elm-tree; they had them on all the fences and the garden paling, and they would shoot awhile at one mark, then change to another, and I never knew exactly where they would be shooting next, and I hardly dared go to the well for water, or to the woodhouse for wood, and it seemed more than ever like living in a fort.

But, the darkest hour is just before the dawning; they soon went west, and for six years I have breathed freely—never having to dodge a shot nor tremble at the sound of a gun. But now, alas! can Providence have the same trials in store for me? am I to go out of quiet, peaceful life, into another fort? Am I to be shot at, shot over, and shot un-

der? Am I to rise up in the morning and lie down at night to the music of the shot gun? Will the boards with bits of white paper tacked on them spring up all over our dooryard, and be leaning up against trees and fences? Shall I be called upon to act as hospital surgeon every time the gun kicks? and shall I, oh! shall I be expected to be blind to every shot that misses, and to rejoice in all that hit? For now our boy is big, and he wants a gun; he doesn't want it as the girls want ribbons and rings, but he wants it as if his very life depended on it. When any one mentions a gun, he sighs; and if he hears a shot he turns pale to the lips; and when the wild geese and ducks fly over in the spring and fall, flying low down so that we can see the colors, and tell the drakes from the ducks, he goes off by himself so that we may not see him cry. He wants a gun just that bad, and now what am I to do? Tell me, all you that have boys.

Vermont, Ill., Jan., 1885.

MAHALA B. CHADDOCK.

THE TWO THINGS THAT JOHN HAS DONE DURING THE PAST YEAR.

THAT IS, WHAT HE HAS DONE IN THE BEE BUSINESS.

ALL I have done this year is two things; viz., I went to town one day and found a crowd collected around a small tree. I saw pretty soon that it was bees they were watching. They had already taken the most of the bees to the harness-maker's house, he being the first one to see them. There was about a halfpint left, and I said to the boy that was with me, "George, let's take the rest of these bees to Mr. Smith the harness-maker."

"All right," said he, and I held my hat under the limb, and he shook it, and the bees all fell in my hat.

We took the bees and put them in the hive and came on down town. About three weeks after that, one of the neighbors who has black bees came to borrow our smoker. Their bees are in the house, in a hive about 7 ft. long and 6 ft. high, with a door that you can walk in at.

When they came and asked for the smoker I concluded to go and rob their bees for them, therefore I got mamma's veil and a pair of gloves, and started. When I got there I lighted the smoker and walked in, and began to smoke them off the combs.

The bees began to sing, and made an uproar like an engine letting off steam. I got about six gallons for them, and got stung only once.

After I had taken out two or three gallons, I started in and knelt down. I had on linen pants, and I knelt down on a bee, and he made me know he was under my knee. One bee got inside the veil, but I had seen in GLEANINGS for that month that bees, when they got inside a veil, were always anxious to get out, and it did not scare me much.

These two things are all I have done this year working at bees. At the beginning of last spring, a year ago, mamma got a hive of bees of Mr. Theobald, of Centerville, a town about 6 miles from here. She made it a rule to open the hive once a day, and papa said that we had better leave the bees alone, as they did not do as well, he said, as when they were left alone. After awhile he took an interest in bees, and would open the hive once, and sometimes three and four times a day.

New Vienna, Ohio.

WM. M. NORDYKE.

THE WASTE-BASKET.

There's a specter tall and gloomy,
In the sanetum of the Ed,
Standing in a darksome corner,
With its ghastly mouth outspread.
'Tis more frightful, more forbidding,
Than a phantom of the dead;
It has caused more real terror,
Filled more hearts with quaking dread,
Than any fancied, fiery demon
Of a mind with reason fled,
Yet this horror of all writers
Is the best friend of the Ed.
Many hearts have quaked and quivered,
Many eyes have torrents shed,
When they found their fabled genius
Swallowed by this specter dread.
Oh could I tell each writer
Of our GLEANINGS here to-day,
That this greedy, cruel monster
Had departed, flown away,
Left the corner in the sanetum,
Never more with us to stay,
What a shout, what grand hosannas,
Would go up along the way!
But, then, may we speak the sentence?
Would it not cause more dismay,
Should this specter, at our bidding,
Close its mouth and soar away?
Could our Editor survive it?
Could he live one single day,
If his best friend were denied him,
His sole prop cast away?
Come to think, it would be better
To yield gracefully to fate;
So I'll send these verses forthwith,
Though they leave me desolate.
Never more I hope to see them,
In the mystic form called fame,
But to satiate this monster,
Go my verses and my name.

Selected and modified to suit GLEANINGS, by

W. W. ADDISON.

Friend A. and others. I have often thought what a nice thing it would be to publish every thing that might be sent in—good, bad, and indifferent, thus virtually annihilating the waste-basket, as you are pleased to term it. But, would our subscribers be satisfied? GLEANINGS would not only be so voluminous that very few could read it, but, worse still, I am afraid a still smaller few would be willing to pay the expense of putting every thing in print. I do not see but it is one of the laws of nature, that the fittest must survive and the others go to the wall. I will tell you how to get your communications into print, and at present I do not believe there will be much trouble in any case, if you go according to the following rules:

1. Do not write until you have something to tell; and when you tell it, tell it in the fewest words you can, keeping constantly in mind that many other brothers probably have something good to tell, and want a chance too.

2. Put a heading on every article, if you please, and then stick to your head; that is, do not mix up things; or if you must mix them up, make a little sub-head to the different subjects you touch on. Write plainly, and punctuate it as you want it.

3. Write for the good of your fellow-men, and for the glory of God, not to show how smart you are, nor with the view of getting money for what you write. The latter is all well in its place, but the first motive should be doing good to your fellow-men, and the money part will follow of itself.

4. Above all, be brief, especially if you are new at the business. When you are recognized as a regular paid contributor, then it is very well to write several pages, if you have enough worth telling to cover several pages.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows: viz.: *Sheep, O! The Giant-Killer*; *The Roby Family, Rescued from Egypt*; and *Ten Nights in a Bar-Room*. We have now in stock *Our Homes, Part I*, and *Our Homes, Part II*, which will be sent the same as the above. Besides the above books, you may have a photograph of our old house apia, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any of the above pictures for every letter that gives us some valuable piece of information.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

But whoso shall offend one of these little ones which believe on me, it were better for him that a mill-stone were hanged about his neck, and that he were drowned in the depth of the sea. *MATT. 18: 6.*

HUBER is now getting to be large enough to talk, and ask questions; and, oh my! doesn't he just make use of his little tongue! One thing impresses me now, very strongly—how wonderfully like wax are these little minds, taking and storing impressions! and the solemn part of it is, that their little minds are just as ready to take in bad impressions as good. How very, very careful, then, ought we to be, how we act, and what we say and do before the little ones!

A few days ago, in trying to put on his mittens I spoke to him about his thumb. Then I asked him, "Where is thumb?" By way of reply he put his hand down and pointed to one of his fat toes. "No, no," said I, "that is *toe*. Where is *thumb*?" holding it up before him. Now, he did not know about thumbs and toes, but he had learned by sad experience where the kitchen *stove* was; so he replied, "*There, toe*." And it was quite a time before I could make him comprehend the difference between "toe" and "stove." His mamma made him comprehend it, however; and when I came home he was very much pleased to tell me that there was the *stove* over there, and here was a *toe* right down on the little foot.

The weather has been very cold for a few weeks, so he could not get down to the pond, and his greatest delight has been to visit the little greenhouse that belongs to the factory. We all have dinner at the factory, with the hands; and after dinner I have generally taken him down to the greenhouse, then let him see the big engine when it starts up at half-past twelve. After about three times he learned the programme, and so he would

begin along in the forenoon to tease. "Dimmy, papa: dimmy, papa." He would keep saying it over and over; and finally when his mamma took him over, after a bite or two, he commenced, "Papa, gagen," meaning that he wanted to see papa's garden; and the dinner wasn't anywhere, in consequence, compared with the wonderful sight in the greenhouse, of the little plants just pushing through their earthy covering, and enlarging day by day, so rapidly that even his little mind comprehended that very soon there would be "num nums" to eat. No wonder he loves the garden. During these sunshiny January days, when the thermometer is down to zero, or lower, the "gagen" is even to me the most enticing place I know of.

A few Sundays ago he got hold of one of my collars of the previous week, and got it around his chubby neck, and was happy for a couple of hours in the possession of a "callow" like papa's. The next Sunday, just as soon as it was evident that I was going to stay with him instead of going off to the factory, he began to tease for "callow" again, and now he calls every thing "callow." Even the white wristbands are "callows," with every thing else of the sort. The same way he calls every puddle of water a pond, even if it is not bigger than a cow-track. Bodies of water are ponds, and he never tires of talking about ponds, and having every thing pertaining thereto explained to him.

Now, then, what a wonderful opportunity of teaching truth, purity, love, and kindness! Do you see it? Suppose his little ears are witness to quarrels and harshness, obscene and blasphemous words, cruelty and falsehood, is it not fair to presume that he would catch hold of these things just as quickly as he grasps holds, and dwells on "gagens," "callows," ponds, and the like? Shall we not, then, be very very careful?

But whoso shall offend one of these little ones which believe on me, it were better for him that a mill-stone were hanged about his neck, and that he were drowned in the depth of the sea.

500 LBS. OF HONEY FROM 15 SWARMS OF BEES.

I am a father's boy. We have 15 swarms of bees. We got 500 lbs. of honey. C. H. GETTLEY, age 13, Wooster, O., Nov. 30, 1884.

FROM 25 TO 27, AND ONLY 125 LBS. OF HONEY.

My father has 25 hives of bees; he got only two natural swarms. It was a very poor season. He took only 125 lbs. of honey. CARRIE WILLIS, Yocumtown, Pa., Jan. 1, 1885.

SARAH'S SHORT LETTER.

Uncle John keeps bees, and he made a bees-cellar. My uncle's name is John Walden. He has your bee-book. SARAH D. BARLOW, Northfield, Minn.

3200 LBS. OF HONEY FROM 77 STANDS OF BEES.

My pa has 77 stands of bees; we took 3200 lbs. of honey. Pa gave me 5 stands of bees, and somebody stole one. Ma and pa went to California, and they went to the ocean and Cliff house and saw the sea-lions. The bees were working on the gum-tree blossoms, and the bees that they have out there are little black fellows. PAUL LATHAN,

Papillion, Neb., January 24, 1885.

A LETTER FROM A 7-YEAR-OLD FRIEND.

I have been reading about Huber to-night. I have to stop and laugh a little, and then I lose the place. Please write more about him.

Key, O., Jan. 16, 1885. NORA NEFF, age 7.

A COLT THAT WILL SHAKE HANDS WITH THE BOYS.

I am a farmer's daughter. My pa keeps bees; he has 16 swarms. I go to school, and help my ma do the work nights and mornings. We have a colt here, and it gives the boys its front foot, to shake hands with them. It is a great pet.

Yocumtown, Pa. CECILIA FETROW, age 10.

TWO LITTLE LETTERS FROM TWO LITTLE BOYS, JUST AS THEY WROTE THEM, AS NEAR AS WE CAN FIX IT.

I AM A LITTLE BOY SIX YEARS OLD MY PA KEEPS BEES THEY ARE NOW IN THE CELLAR. IN THE SUMMER HE KEEPS THEM IN THE BEE HOUSE GARDENVILLE, NY HENRY LEHDE

I AM A LITTLE BOY FOUR YEARS OLD MY PA KEEPS ITALIAN BEES I HAVE A LITTLE SISTER TWO YEARS OLD SHE HAS BLUE EYES WE ALL LIKE HONEY EDWIN LEHDE

GARDENVILLE NY JAN 22 1885

WILLIE'S SAD LETTER.

My father keeps bees; he has 26 colonies. They did not do very well. Last year was almost a failure. My pa had lots of discouragement last summer. Our house burned down, and we lost our little sister. I go to school every day, and Sabbath-school.

WILLIE SHILLING, age 11.

Jewett, O., Jan. 26, 1885.

FRANKIE'S ACCOUNT OF THE WAY THEY CATCH LAKE TROUT UP IN MICHIGAN.

I live near Lake Huron, which is one of the largest fish-ponds in America. When there is ice on the lake, men cut holes in it and let down a little wooden fish, and the lake trout gather around it, and the men spear them. Papa takes GLEANINGS, and likes to read the children's letters.

Oscoda, Mich. FRANKIE F. BRADLEY.

DORA'S LETTER—4800 LBS. OF HONEY FROM 94 COLONIES.

Pa has a farm of 80 acres, and he keeps bees. He has 94 colonies. He got 4800 lbs. of honey last summer. He has got a horse-power and sawing-machine to make bee-hives and honey-boxes. I like to see him saw. I have two sisters and three brothers, and we have an organ.

DORA TENANT, age 10.

Eureka, Wis., Jan. 23, 1885.

NIGGER, THE DUCKS, AND THE DINNER.

Papa has 4 bee-hives; he commenced with one hive. I have a cat and a dog. My dog's name is Nigger, and he killed two ducks. La! but we had a good dinner.

JOHN C. HUGHES, age 12.

TWO LITTLE LETTERS FROM TWO BROTHERS AND SISTERS.

Uncle Amos, I read in papa's GLEANINGS about little children writing to you, so I thought I would try. I have a little sister. Her name is Lydia. I have some ducks. I go to school this winter. I have been sick, and I have been having lots of fun since I have got so I can use playthings. I have 2 chickens; they are pets. GERTRUDE HALL, age 7.

Papa has had very good luck with bees. He says he will make a fish-pond. He has a very good place.

I think one of our neighbors says he would not take \$100 if he had it.

CHARLEY HALL, age 9.

Boothsville, W. Va., Jan. 30, 1885.

A REPORT DISCOURAGING.

My brothers have 3 hives of bees. I like honey, but we did not get any this year. Can I have a book? I am five years old. WILLIE CLEVELAND.

Collamer, Cuy. Co., O., Dec. 9, 1884.

Well, Willie, it seems to me that is a little sad. Your brothers with three hives of bees did not have any honey to give you at all.

SIX-YEAR-OLD ADDA'S LITTLE LETTER.

Well, Uncle Amos, I am a little girl six years old. My pa keeps bees. He has two colonies. He got 1800 lbs. of honey. It was in the comb. I have a little bantam rooster. He weighs 11 ounces. His name is James Blaine.

ADDA BROWN.

Sebewa, Mich.

2500 LBS. OF HONEY FROM 75 COLONIES.

My father keeps bees; he has 75 swarms; we had 2500 lbs. of honey. We have them all in the cellar. I have 4 bantams. My sister and I have a black calf; her name is Hollie. I like the book you sent me.

LUCY TALCOTT.

Owego, N. Y. Feb. 1, 1885.

SAMUEL'S CONTRIBUTION IN THE WAY OF VALUABLE FACTS.

We have a cow that had a great big wart in her ear; so pa said that if I would take it off he would give me a quarter. So I applied kerosene oil every other day, and I took it off in about three weeks. If this is worth a book, please send me the Roby Family.

SAMUEL L. BURNETT, age 14.

New Vernon, Pa., Jan. 15, 1885.

Very good, friend Samuel. If kerosene works on all the cows as it did on yours, the idea is certainly worth a five-cent book.

LOUISA'S REPORT.

We had 500 lbs. of white-clover and basswood honey, all in one-pound sections, and about 75 lbs. of dark honey. It is all sold but 24 boxes of white-clover honey. We sold it all near home—the white-clover and basswood honey for 16 cts. a pound, and the dark for 12 cts. The above is from 7 colonies of black bees. Our bees are wintering on summer stands, packed with forest-leaves around them. They had a good fly last week, and are all right.

LOUISA A. RINDSACH, age 13.

N. Ridgeville, O., Jan. 13, 1885.

EVA'S IDEAS IN REGARD TO LOW PRICES.

I live with Mr. Packwood, and he has bees. He made about 15 barrels of honey this season. The bees made plenty of honey; but the trouble is, they send it away, and do not get a good price for it; but I suppose you know that yourself. Don't you think it is hard for men that work as hard as they do? But, however, they keep up spirits, and I think there will be a good many bee-men this summer. My papa is going to have a few hives for his own use. I hope he will, for I like to tend to them myself.

EVA S. GLAWSON.

New Smyrna, Fla., Jan. 12, 1885.

Why, Eva, I suppose it is only human to want a good price for every thing we have to sell; but then, you see when we want to buy something that somebody else raised, we rejoice at low prices, and so there are two sides to the question. Now, I suppose

the golden mean would be about such a price as would do the most good to all classes of people, and that would be what we call a *fair* price, would it not? Low prices are hard for the producer, but a blessing to the consumer; so it is not all a misfortune when prices run low.

TEA AS A HONEY-PLANT.

I thank you for that book you sent me. Our bees have been at work for the last two or three weeks, and we have had pleasant weather this far. The bees have been bringing in pollen and honey. I have seen them on roses, tea-blossoms, and palmettos and peach-blossoms. I send you a tea-blossom. May be you have never seen any before. I hope the blossom will reach you in good order.

Francis, Fla., Jan. 4, 1885. CHARLES LEYVRAZ.

Many thanks, my little friend, for the tea-blossom. Isn't that a novelty, that bees work on the blossoms of the plant that bears the tea we use on our tables? I wonder if we hadn't better run opposition to the brethren in China, and commence raising it so as to get honey.

THE WAY JOHN HATCHES QUEEN-CELLS UNDER A SITTING HEN.

Our bees are all in good condition now. I forgot to tell you that we had 49 colonies of bees and two Italian queens in nucleus boxes. The little swarms died. I put the royal cells in small wire cages when I put them under the old hen. We have a good place to sell queens and honey too. Our bees can not make enough honey to fill orders. We charge \$1.00 for untested queens, and \$2.00 for tested. I thank you very much for that book you sent me. My leg is all right now. I go to school. I went into a larger spelling-book to-day. JOHN ROBERTS.

Schoolhill, Wis., Jan. 26, 1885.

NELLIE'S LETTER, FROM A TOWN WHERE A SALOON HAS NEVER BEEN KEPT.

Papa kept bees in Iowa, and now we intend to keep them in Nebraska. We came out here last fall and brought one swarm with us. They are still alive, and out for a fly yesterday. Some people say bees won't live here; but I guess they will if they get a chance. Papa had 20 swarms in Iowa. I have been reading some in natural history, and it says that cucumbers and squashes won't grow without the bees; is this item new and useful? And now I want to say a word for our fast-growing town. Our town lies on the Burlington railroad; has 700 inhabitants, two churches, and a Congregational academy. There is not, and never has been a saloon here; and if any of your readers wish to go west, and would like to give their children a Christian education, Franklin is the place to come to.

Franklin, Neb., Jan. 31, 1885. NELLIE FAY, age 10.

Well, Nellie, your concluding fact is not only valuable, but it is a cheering and encouraging one.

KEEPING BEES TOO WARM IN WINTER.

My pa has 11 swarms, 6 in big boxes with old carpet and rags on top, and 5 in Simplicity boxes with leaves all over them. I must keep the holes open for the bees, my pa says so; my grandpa has 20 straw baskets with bees in, and big bundles of straw over them to keep them warm. Last winter 8 died. My pa says he makes them too warm. Is that so? Grandpa is 70 years old. I like him. He gives me

lots of apples and cider when I go up the valley to see him. I like to read the letters in your books that my pa gets from you. FREDDIE W. REX.

Lehighton, Pa., Jan. 22, 1885.

I hardly think, Freddie, that your grandpa keeps the bees too warm by covering them with straw. Is there not some other cause of their dying?—Somehow I feel a little sorry when you say you drink cider when you go to see your grandpa. Cider makes so much trouble with people who have a leaning toward intemperate habits, that most of the people nowadays have decided to get along without it. Don't you think it is a better way, Freddie?

MINNIE'S PET RABBITS.

I notice in GLEANINGS of Dec. 15, that Mr. Fradenburg sent you a pair of rabbits. Well, I will tell you about mine. Last summer, one evening I was sitting on the lawn, and my kitty came along with something in his mouth. I looked, and it was a little rabbit. Although it was a wild one, it made a nice pet. I fed it, and it grew so it could run around, and then we made a yard for it close to the house. We left it out at night a couple of times, and so one morning I went out to feed it, and could find it no place. Then I saw some fur and blood around in the pen, and we supposed it was a cat that killed it, for we saw a cat sneaking around the pen several evenings after that. Its name was Bunny. What were your rabbits' names? I felt very badly about it, but I will soon get a pair of tame rabbits. MINNIE RHODES, age 12.

Wilmot, Ohio.

Isn't it a little singular, Minnie, that your kitty carried the young rabbit in that way without killing it? I believe it is true, however, that cats do sometimes take care of rabbits, or even chickens, about as they would a kitten of their own. I am sorry to know that poor little Bunny was killed by a cat at last. We call our rabbits Bunny too, and you ought to see Huber tease to go and see them.

VERSES COMPOSED BY LITTLE 10-YEAR OLD CARRIE, ON THE DEATH OF HER BROTHER.

Mamma has 5 stands of bees, and papa makes beehives to sell. Mamma gave each of her children a stand of bees. My stand swarmed, but died. Papa packed his stands in planer shavings, and they kept well. I have a sister to play with. She is a little girl, but I love her very well. I have 8 brothers. The one that was our bee-man that helped mamma hive bees when papa is away from home died. The verses, I composed. I go to school; am in the fifth reader. I am 11 years old; I was 10 when I composed my verses.

IN MEMORY OF MY BROTHER.

There is a place to me most dear,
The evergreens are growing there.
My dearest brother there must be,
Although his form I can not see.
Four evergreens were planted there,
And they were growing green and fair.
When to this sacred place I strayed,
Behold! one evergreen is dead.
There is a vacant place, I said;
And in our home a vacant bed.
Then to this tree I softly said,
"You, like my brother, too, are dead."

REFRAIN.

We can plant the tree that will,
But brother's place there's none can fill.

CARRIE M. SWARTZ.

Schultzville, Pa., Jan. 26, 1885.

100 SWARMS OF BEES, SOME ROUEN DUCKS, AND A WHITE COON BESIDES.

Pa has 100 swarms of bees, and he raises and sells queens. My brother Byron caught a white coon. We have it for a pet. We have 9 big ducks. They are called Rouen ducks. T. PALMER BLANK.
Woodville, Ohio.

32 BELOW ZERO; KEEPING BEES IN A FRUIT-HOUSE.
We have 31 colonies of bees in the dooryard, and a few weak ones in their hives in the fruit-house. The thermometer marks six degrees below zero now, and day before yesterday it was 24 below. Yesterday morning the thermometer was 32° below zero.

HARMON K. HOCKETT, age 11.

Jonesboro, Ind., Jan. 21, 1885.

Now, my little friend Harmon, you have told something that I just want to know about—why will not fruit-houses be just the thing to keep bees? Please let us know how you winter.

ROSA'S BROTHERS AND THE BEES.

My brother had 6 stands of bees in the spring, and in the fall he had 14. Ma and I help him to hive his bees when they swarm. He has good luck with bees. They don't fight him and sting him any. He takes GLEANINGS, and I like to read it. One of our neighbors got him to take 11 stands of his bees. He is afraid of them himself, but he likes the honey. He will keep them for a share.

Downs, Ill.

ROSA CURTIS, age 12.

RAY AND HIS PAPA, AND THE 200 COLONIES OF BEES.

I am but a boy eight years old. My name is Ray. I go to school, and learn to read and write and spell, and mornings and evenings I help my papa feed the sheep and mules and cattle and pigs, and evenings I carry in the wood for my ma. In the summer I help my pa make sections and sash. My pa keeps about 200 colonies of bees.

Ada, O., Jan. 26, 1885.

RAY MURRAY.

DOLLY AND HER GRANDPA, AND THE 80 SWARMS OF BEES.

My grandpa has about 80 stands of bees, and they make lots of honey. When they swarm, sometimes they want to go away, and grandpa gets the queen and takes off part of one wing, and then she stays at home, and of course the rest stay with her. Perhaps my mamma will have bees some day, and I will know more about them, and can write a better letter.

DOLLY OBENSHAIN, age 9.

Bloomington, Ill., Jan. 26, 1885.

FROM 40 TO 75, AND 1800 LBS. OF HONEY.

My papa has 75 swarms of bees; he had 40 to begin with last spring. Mamma hived 3 swarms of bees last summer. Papa buried some last fall. They are keeping nicely this winter. He had 50 swarms once, and they all died; but he got some more. The bees made 1800 lbs. of honey last summer. I pieced a quilt on the machine. I have a large doll. I wrote this letter all alone. I have been to school for 8 months.

LINNIE E. DOANE, age 8.

Pipestone, Mich., Jan. 26, 1885.

RESUSCITATING BEES FOUND ON THE SNOW, BY WARMING THEM.

We started with two swarms of hybrids last spring, and increased to six. Papa found some apparently dead bees on the alighting-boards of his hives, and brought them into the warm house, and

put them into an observatory hive, and many of them revived, which proves Mr. Swinton's advice about queens to be good. Papa set some boards up in front of his hives, to keep the sun from shining in and tempting them out these cold days.

LUNA A. PARKER, age 12.

Lockport, N. Y., Nov. 25, 1884.

PLACING THE ENTRANCE TO THE NORTH, ETC.

My name is Edith Mindwell, and I have a brother called Roswell. We have a large raspberry-patch near the bee-house. I go to school, and I am in the fourth grade. Papa thinks his bees do better facing the north, winter and summer.

E. M. PHELPS, age 10.

Galena, Md., Jan. 24, 1885.

Perhaps your pa thinks that, by placing the entrance to the north, the bees are not so apt to fly out during unseasonable weather. Is it not so, friend Edith?

A CURE FOR BEE-STINGS.

My name is Roswell Phelps. I help my papa pack his honey, which he sent away in boxes. He bought the boxes of you. I try to help my papa and mamma a great deal. I know a cure for bee-stings. When a bee stings you, suck out the poison, or get some one else to do so. ROSWELL PHELPS, age 7.

Galena, Md., Jan. 24, 1885.

Perhaps, my little friend Roswell, sucking out the poison, or trying to, won't do any harm; but I believe I would rather let it alone, and not do anything after getting out the sting. If one *must* do something, however, I do not know but your remedy does as well as any.

HATCHING QUEEN-CELLS IN AN INCUBATOR.

Last summer pa and I hatched queens in the incubator while we were hatching chickens; and when we had hatched all of them, pa made a queen-incubator, and put it on top of a hive, and filled it full of queen-cells; and when a colony did not have any queen we would take one out of the incubator and put it in the hive. This may not be new to you, but it may be useful to some of the other writers. I hope the writers who have incubators will try it next summer. Pa and I think it is a better way than to let them hatch in the hive.

EDGAR KENNEDY.

Montclair, Hendricks Co., Ind., Jan. 23, 1885.

A LETTER FROM A LITTLE ORPHAN GIRL.

I am a little orphan girl 11 years old. My home is with Mr. Eli Reeves. He got me out of the orphan home in Louisville. I call him papa. He has 31 stands of bees now. Last spring he started out with about 15. I think he forgot to keep account of the honey. I am very fond of honey. We don't use any tobacco at our house, but papa smokes. I am afraid of the little bees. I have been stung some two or three times, but think I shall get used to it.

MAUD FRENCH.

Cayce, Ky., Jan. 26, 1885.

BEES, STRAWBERRIES, TURKEYS, STEAM-ENGINES, ETC.

My brother Christian keeps bees. He has 32 colonies. My brother John has one colony. He paid one dollar for it. He paid 10 cents for a queen-cell. He gave me two frames of hatching brood. I sawed out the boards for a hive. My brother Christian nailed it together, so I have one colony. I packed it outside with straw, inside with chaff. My brother

Christian raises strawberries. I go to school; we have a good teacher. We have an engine from Massillon; it works well. We raise poultry. We sold some turkeys. CONRAD E. WICKESSEK.

Marshallville, Ohio, Nov. 27, 1884.

ROBERT'S COMPOSITION ABOUT BEES.

The bee is as large as a horse-fly; they are very industrious insects. Wild bees live in hollow trees; tame ones live in hives. They make honey from the sweet-William, roses, columbines, daffodils, sun-flowers, pinks, goldenrod, buckwheat, and linn. They get rid of all the drones in the fall; they do not want them to eat the honey that they did not help to gather. They will not sting you if you do not harm them. Bees are found in most parts of the country. There is but one queen in a hive.

Glidden, Ia.

ROBERT DREW.

A FOLLOWER OF THE SAVIOR ALTHOUGH BUT 9 YEARS OF AGE.

I see in a catalogue you sent papa, that you had two kinds of cards you send to little folks free of charge—one kind against profanity, and one with a child's prayer on. Will you please be so kind as to send me some of both kinds? I am a little girl nine years old. I know the Lord's prayer by heart, and say it every night. I am very anxious to see the little prayer you have so kindly selected for little folks. I am trying to be a good little girl, so that the Savior will be pleased with me every day.

DORA L. B. FISHER.

Salisbury, N. C., Jan. 26, 1885.

JENNIE'S LETTER ABOUT THE PEACHES.

My papa has bought 3 colonies of Italians and 4 colonies of black bees, so you see we intend to raise bees, and have honey in our country home. We have a great deal of fruit. Our Amsden peaches get ripe June 1st. Would you like a box about that time this year? We enjoy reading GLEANINGS, and especially the boys' and girls' column. We all go to Sunday-school.

JENNIE C. REED.

Huffman, Ala.

To be sure, I should like a sample of your peaches, friend Jennie, and they would be a great novelty here, I tell you, at any time in the month of June. Many thanks for your thoughtfulness of Uncle Amos.

FROM 9 TO 17, AND 350 LBS. OF HONEY, ETC.

We began last spring with 9 colonies of bees; increased to 17, and got about 350 lbs. of honey. It was not a very good season for honey. Pa got a Holy-Land queen of you last July, and raised a queen from it, and the one he raised began to lay in September. We have got her in a nucleus, with about a quart of bees, and they have wintered well so far. Pa feeds them candy. We hatched a queen under a hen last summer. We took a little box, and put a few small holes in it, and then lined it with cotton, and then put the queen-cell in the box. Last summer two swarms came out together; and when pa tried to hive them they both went back to their old hives.

ELLEN YOCUM, age 12.

Riverton, Ill., Jan. 24, 1885.

WHAT A 5-CENT MOUSE-TRAP DID AWAY OUT IN CALIFORNIA, ETC.

We got a 5-cent mouse-trap of you, and we have caught twelve troublesome mice already. California is a good place for bees. They are working even now in the flower garden, on pea flowers and blue-gum flowers. We didn't have much nice honey in

1884. Our best honey was sage in the comb, but most of that we had was "hot." One day when we were eating dinner my papa and brother Alfred were not at home, and suddenly we heard a swarm of bees passing. We jumped up and followed them one-fourth of a mile, and threw some dirt at them. Soon they settled on a small tree; my sister and I got a hive, and shook them into it. We had a little trouble with them, but managed to get them home early next morning, only to find the hive empty. They were a "crazy swarm," and had left.

LILLIAN HINDE, age 12.

Anaheim, Cal., Dec. 26, 1884.

40 KINDS OF TAME STRAWBERRIES, AND SOME OTHER THINGS.

My father has 40 colonies of bees. We have 40 kinds of tame strawberries, and a great many kinds of raspberries, blackberries, and grapes. We live on a farm of 153 acres, and it is about 5 miles from Mendville. I can not tell how old Harvey Baer is. Father says there is an error in it. Papa is an old teacher. I have no brothers nor sisters. Our hired man's name is Jim, and he has worked for us four years. Papa is secretary of the Farmer's Club, and writes for papers, so I will write for your paper. Mamma said that if I wrote for your paper again I should tell you how many pounds of honey we got this year.

CLARENCE H. LEFEVER, age 10.

Hayfield, Pa., Jan. 27, 1885.

In Harvey's problem, he should have omitted the three first words, and begun with the fraction $\frac{1}{2}$. Of course, the whole of a thing plus a part of it can not equal the thing itself. His age is 12.

HARVEY'S PROBLEM, AGAIN: A GOOD REPORT.

As I have worked out Harvey's example, which gives me 12 years, which I think is correct, I will send our report for last year. We increased from 60 to 100 hives, and took 4000 lbs. of honey, mostly extracted. The bees stored a nice lot of bitter honey, in the fall, which was not fit for table use, but is fine for wintering bees. They are all in fine condition. They were bringing in pollen from the elm on the 10th of Jan. CLAUDE E. BROGDON, age 12.

Bryan, Texas, Jan. 23, 1885.

Friend Claude, you will see by the letter above this, that your answer is correct.

\$22.60 WORTH OF HONEY FROM ONE HIVE IN ONE SEASON.

Pa is a bee-keeper, and has been keeping bees since 1875. He has between 50 and 60 colonies of bees, and has had as high as five swarms a day. The best he ever had from one hive in one season was 16 large boxes of honey that he sold for \$22.60. Pa has a large-sized extractor that he ordered from Cincinnati. He has a shop, and he makes all of his bee-hives, frames, boxes, and does all of his painting. I have to watch the bees; and when they swarm, and pa is not at home, I have to hive them. I have been stung hiving them but once or twice in my life. One day when pa was gone, and I was too little to hive bees, ma hived four swarms in one day. Pa has a bee-smoker, but he did not get it by quitting the use of tobacco. He smoked and chewed seven years, and thought it was hurting him, and he quit ten years ago last May, without a smoker, and has not tasted it since. He neither smokes nor chews, nor drinks any intoxicating liquor or coffee. He is a wholesouled Prohibitionist. He

says any one can, if he will, quit the use of tobacco and whisky. Please send me cards against profanity.

ALICE JONES, age 14.

Sedalia, Mo., Jan. 31, 1885.

WHY HONEY FROM SPANISH NEEDLE DOES NOT CANDY THIS YEAR, ETC.

Our bees have been shut up for two months, on account of cold weather, with the exception of one day two or three weeks ago, when they had a fly in the middle of the day. They showed signs of a great many dead ones. All the bees in this part are on their summer stands, and generally without any protection. Will you please tell me why pure Spanish-needle honey doesn't candy this year?

Iola, Ill.

CORA LONG.

I do not know why the honey does not candy, friend Cora. That seems to be an accidental property. The honey from some plants remains persistently a liquid; and, again, the honey from the same plant will candy one season, and the next season it will not. I suppose that, by some accident in nature, the honey that does not candy contains a different proportion of dextrine in its make-up. The lot that does not candy is like the liquid glucose, and that that does candy is more like its solid near relative, grape sugar.

LAURA'S LETTER ABOUT HER PAPA, WHO IS DEAD.

I go to school. I study reading, spelling, and writing. I have two brothers, one 16 years old and one ten, and two little sisters. My papa kept bees. He is dead now. He died last May. Oh how we miss him! We have 16 colonies of bees. Mother takes care of them. She wants to sell most of them, as she is not able to take care of so many. Our bees didn't swarm much last summer. My papa used to take GLEANINGS, and we all liked it. We would take it now, but mother thinks she is not able to. My papa was a soldier, and got a pension, now we get it. We are getting along pretty well. I should like to read some of your nice books.

LAURA WILLIAMSON, age 7.

Willow Island, W. Va., Jan. 29, 1885.

May God help you, my little friend Laura, and your poor afflicted mother, and all the rest of you, in your loneliness. By reading your little letter I was led to wondering what little Huber would say, and how sad he would feel, if his papa were taken away as yours is; and while reading it, it seems to come over me as it never did before, what a sad, sad thing it must be for little children like you to lose their dear papa, nevermore to see him in this world. Tell your good mamma that I will gladly send her GLEANINGS for one year, for your little letter, and I will send it to her with the prayer that it may help her some with the bees, in the absence of that companion whose place nothing in this world can ever fully supply. May God's blessing be with you all.

BEE-KEEPING FOR SCHOOL-TEACHERS.

Two years ago papa put camphor gum in the hives, and he didn't have any trouble with the moths, and this year he kept neglecting it, and the moths killed two or three swarms. Last summer he had only 15 swarms, and now he has 24. In the summer he lost three swarms, which left. Sometimes he has two swarms come out at once, and they all cluster in one place. My eldest sister at home is

learning to hive bees, and she is teaching school this winter. She thought teaching and bee-keeping would go well together, because she said she could teach in the winter and tend to the bees in the summer. As they have only seven months of school, five for the winter term and two for the spring term, she thought she would have time to tend to bees in the summer.

DAISY PHELPS, age 12.

Springfield, Ill., Jan. 20, 1885.

Friend Daisy, I think bee-keeping will be tiptop for your sister, for any man or woman who can take care of a school full of children would probably be able to manage the honey-bees.—You do not want any camphor about your hives, to keep moths away; in fact, I do not believe much in medicine of any kind to keep away insect-enemies. Have your hives so they can be opened easily and quickly, and give the bees a fair chance, and they will take care of the moths themselves, and I believe the same rule will apply to insects that trouble our plants and vegetables. Give the plants such a good start in life that they will take care of themselves in spite of the insects. With potato-bugs, pitch into them with such vehemence when they first show their "noses," that you scare them to death in the outset, and save the money you would have to pay for Paris green. I do not believe the camphor would bother the moths at all.

TEACHING MAMMA TO SKATE ON THE CARP-POND.

I like your description of the carp-pond. I went to skate on my papa's pond, and fell and cut my knee so badly that I have been a cripple for some time. I will not skate any more this winter. Papa took mamma down to the pond to skate, but she tumbled around so she kept the children laughing themselves almost to death. He gave it up as a bad job, trying to teach an old lady to skate. She was raised where there was neither snow nor ice. I should like to pull Huber and my little brother on the sled. My brother is older than Huber.

HOW TO CURE FROSTED FEET.

As there are so many people with frosted feet this winter, I will tell you a cure for them. Get the green moss off the roots of the forest-trees; put it in a pot, and cover with water. When it boils, place the feet over the pot while the steam is rising; keep a blanket wrapped around, to keep the steam in. It will be painful for a few minutes, but will cure them.

PEARL TYLER, age 9.

Knob Noster, Mo., Jan. 25, 1885.

You see, Pearl, your mamma did not learn how to skate when she was a girl. Huber's mamma was brought up right close to a river, and she learned to take to ice as ducks take to water. I think what we learn when we are children we seldom forget. Don't you think, Pearl, we ought to be very careful what we learn when we are children?—About your cure for frosted feet, I can not think the moss has any thing to do with it whatever. Suppose you try it without the moss. I am sure you will find it works just the same, unless somebody has so much faith in the moss that it is the *faith* that performs the cure; or, at least, they imagine they are cured, and without the moss they would imagine they were not cured. I do not mean that people are not honest, but only that they get notions sometimes.

OUR HOMES.

Fear not, little flock; for it is your Father's good pleasure to give you the kingdom.—LUKE. 12: 32.

I WANT to talk to-day principally to those out of employment. Those who have plenty to do, and whose time is fully occupied, may listen if they choose; but a large portion of my talk will perhaps not interest them particularly, unless it is through sympathy for their less fortunate fellow-men. Thousands are out of employment, and wanting something to do. I have been told, that in the city of Cleveland alone there are 15,000 people "out of a job," as the saying is. Perhaps many of these are Christian people—people who belong to the various churches, and who are trusting God. How comes it, then, that they should seek in vain for something to do? "By the sweat of thy face shalt thou eat bread," is the command; and yet many all over our land are feeling sad because they can not obey the God-given decree; or, at least, they think they can not, and I hope you will not think me uncharitable when I suggest that people many times make a mistake when they say they can not find any thing to do. This is an old subject, I know, and it is one on which I have talked and written quite frequently, and may be the place which I occupy has a tendency to make me a trifle uncharitable; but every year that is added to my life, strengthens and confirms the position I have been slowly taking, that those who are consistently trusting God will seldom if ever be out of employment; and I can not have very much sympathy for a big strong man who tells me he has searched everywhere, and can find nothing to do. Feeble women, a great many times, seem to have fulfilled almost all the requirements, and yet find difficulty in getting any kind of honest work that will pay even moderate wages. Many times younger people, too, from want of judgment, or because of their youth and inexperience, seem to fail in their efforts to find something to work at. There is another class of people with some property, who become restless and discontented, and say they have nothing to do, and long for something to work at. Sometimes a suggestion, or a little assistance to such, may do them much good.

Did you ever wonder, dear reader, what is to be the ultimate end, if the population of the earth keeps on increasing as it is increasing now? China has given us an illustration, to a certain extent, of the results of "overstocking" (if I may use the word) with the human family. I know some good people who seem to be a little frightened at the prospect; and suggestions have even been made that something ought to be done toward stopping the enormous increase of human beings. I say, these are good people, but I fear they lack faith in God. Our little text of itself ought to cover the ground, and ought to allay their apprehensions. The Creator who planned the universe, and this world with all the rest, certainly included all such contingencies in his plan. And then the question comes up, "What does he

intend to do with us, and what are his plans now?" You see we come on to the question of *trust* here; and before we get through I shall have a little more to say in regard to this. I think his plans are, that we should help ourselves to a much larger extent than we do now. When I see a great strapping youth, or a good stout girl, if you choose, mourning because nobody will give them a job, I feel like saying, "For shame, for shame, my friends. You have no business waiting for anybody to give you a job. Go and get a job yourselves." Very likely the reply would be, "Why, the factories are all full. I have been here and there, and been everywhere, and nobody wants to hire." A big stout German boy told me yesterday he could not get a job anywhere. Just before he came in, a stout strong young man, whose acquaintance I formed in our county jail, came to me saying the same thing. Said I, "Have you been around to the farmers, and inquired for wood to chop?" They both replied that they had, but they could not get a bit of work anywhere. The next day Neighbor H. informed me that he found a whole row of men sitting on the hitching-posts in town, waiting for something to do. Not one of them would go and help him in the woods, during these short winter days, for less than \$1.50 per day. Now, I have no sympathy at all for any one of this class who is out of a job. They ought to be out.

A few weeks ago, one of our neighboring factories shut down, and, of course, many were wanting something to do. A couple of stout young men came to Neighbor H. for something to do, and he told them if he could get wood cut for 50 cents a cord he would set them at work. They cut for him all he intended to have cut, and then made an offer to cut another lot at 45 cents a cord. He took them up, and they were off through the snow before daylight, and worked as long as they could see—worked like "beavers," so he says, and made, perhaps, not much over a dollar a day. This they did while their comrades loafed around the town, probably engaged in sowing the bad seeds, which I have spoken of in another page. Their factory is running now, and, of course, they can do better than to chop wood. But Neighbor H. told me yesterday I might tell every man or boy who came to me in distress, that they could all have wood to chop at 45 cents a cord. Now, then, boys, I presume if I myself were obliged to go out and chop wood at 45 cents a cord, I should not make more than 25 cents a day—at least, for the first few days; but rather than sit around, and say I could not find a job, I would work for the 25 cents a day, willingly; yes, I would work for *twelve and one-half cents a day*; and if I did not earn enough to pay my board, I should at least have the satisfaction of feeling I paid part of it.

I have been accused of being extreme in my views, and perhaps I am; but, thank God, there are a good many who are ready to follow me with their coats off, and their sleeves rolled up, metaphorically speaking. The extreme thing I am going to advocate now is, that we should not only work hard

during all the daylight, but that we should devote our evenings to something that will do us some good, or, better still, that will do our fellow-men some good. I know a great many of you say, "The way we have to work, we are glad to sit down and rest when night comes." My friend, how does your wife or mother do when she sits down to rest at night time? I know of one wife and mother who sits by my side, and darns stockings and such like, after ten o'clock at night too, a great many times. Some of the brethren and sisters employ their time evenings playing progressive eucher—may be you have seen it mentioned in the papers. Well, I have not time to say much about it just now; but I want to suggest something that I think will give you more real solid enjoyment than eucher—progressive or retrograde; and while you are doing it, you may be laying up treasures on earth, and, according to my way of thinking, treasures in heaven besides. To make my meaning clear, I want you to allow me to start off on another track a little while.

Last month I talked to you about being satisfied and contented with what you have already, instead of worrying and reaching and longing and grasping for something else. Well, I have been happy—exceedingly happy, in following out my talk there. Instead of dwelling on something I had not got, and ought not to have just yet, I have been rejoicing with my present possessions—with the things God has given me, and has given all along, that I had forgotten to notice. One prominent thing that I rejoice in is sunshine—I mean the real, genuine sunshine. God pours down upon us without stint, when the days are not cloudy, from morning till night. I always did love sunshine; but I love it more this winter than I ever did before in my life. I love the sun when it first peeps over the tree-tops. I love it because it is one of God's creatures; I love it because *he* sends it to make us happy; I love it because there is such a great lot of it. Of late quite a good deal is said about the sun cure. They cure sick folks by just putting them in the sunshine—nothing else. Well, I think it is good for well folks to be in the sunshine too, that they may stay well. A few days ago one of the girls was down in the greenhouse, looking at some new coleuses that we had just got from Peter Henderson. She said if we wanted the colors to come out bright we must keep them right in the sun, and then these cunning little plants (you know I talked to you about them a while ago) just delight in decomposing the rays of the sun, and sending out to us those gorgeous colors, blended in such beautiful harmony. The colors are simply bits of sunshine which they have caught and held. How beautifully sunshine starts the vegetable world into life! A lot of radishes were started in the greenhouse, with sifted moss and bone dust for a covering, on the plan Henderson gives in his catalogue. They were just peeping above the ground at noon. A little while after, the sun came out of the clouds, and poured his rays right down on them. In an hour or two they had bursted their mossy covering, and pushed

up into his genial rays, in a way that was to me perfectly astonishing. Huber and I both had a "jollification" over them. Well, the sunshine that comes down into that little greenhouse does a lot of good. Pretty soon it will perform the same kind of wonders outdoors, and we may make the broad acres that God has given us, smile and burst forth in bountiful harvests under the influence of this same sunshine. God, in his loving mercy, has given me about 18 acres of expanse on which I may catch sunshine. Under the benefits of modern science we can catch sunshine very much as we catch rain water. We can catch all that falls, if we have a mind to. That reminds me that I have been thanking God, too, for the rain and snow. All the rain that falls on my 18 acres is also my property, and the snow. I can have it to do what I please with it—catch it and make it run into carp-ponds, put it in the cisterns for the stock to drink, or use it for irrigating the plants and vegetables during dry weather, etc. And, by the way, it seems to me that every human being ought to have a little piece of ground he can call his own. I like the idea of having a little bit of land surveyed off and deeded to you according to the laws of our land. May be you can not all have that; but I have been learning to love old mother Earth so much lately that, if I could not have a little bit of real estate, I would have a *box full*, any way, and set it in the window.

Another thing I am thanking God for is the amount of fertilizing material for plants and fruits that is all round about us. When I was going to meeting last evening, the sidewalks were so slippery I walked in the middle of the road. We have had sleighing for about four weeks; and as I walked through town I noticed that the manure from the horses almost covered the white snowy surface in the middle of the road, so much had accumulated in four weeks. Well, this goes on accumulating winter and summer; and Henderson says if you can not get nice soil for plants handily, go and scrape up the dust in the road, over which many teams pass. The roads belong to everybody, and every citizen of the United States has a right to road dust—at least, he has a right to as much as accumulates in the way I have mentioned. If this road dust, when properly dampened for plants, has too much clay in it, make it light with rotten leaves, which nature has thrown about everywhere. Down among our maple-trees we got two large wagon loads of leaves in a short time, and we filled the Jersey cow's stable so full of leaves that, when she lay down on them at night, they almost covered her up. She looks real happy in among them, and expresses her happiness by giving all the milk we can use at home, and in the factory besides. I am thankful for the leaves that are on my 18 acres, that God has sent us. I am going to try to take care of all of them. I can buy manure at the livery stables for 75 cents to a dollar a load; but I feel a great deal happier in using all the fertilizing material that is to be found on our premises, than in paying out cash to somebody else.

There is a peculiar thrill that comes into almost every heart when one first sets foot on a piece of ground he can call his own. When I get tired of writing, or dictating, as I am doing now, I put on my fur cap, and overcoat, and go and look over my 18 acres. A creek runs through the middle of it. I love this creek, even if it does get rampant sometimes, and flood the low ground. There is an excitement in watching it, and preparing for it, and planning carp ponds that will not be injured much by an overflow. And, by the way, when we have a dull time in the fall I set the boys and the horses at work straightening and deepening the channel, and I am in hopes that, after a while, we shall get it so it won't go over the banks at all. Along this little stream we have a side-hill, and some rather steep banks. In one of these banks, protected from the winds, I mean to have a poultry-house, and we are going to push it back into the bosom of old mother Earth, where the "biddies" won't know it is zero outside. I suppose it would be better to have the front of glass, but I think we can make a very cozy place for them without going to the expense of glass, at least yet awhile.

For late strawberries, we want a northern slope. Well, we have got that on the south side of the stream. Alongside of the stream we have rich black loam, just right for celery and other water-loving plants. In another place there is a spring that comes out of the gravelly bed. The water from this spring is going to keep the carp-pond going when we have a drought. Why, almost every day I discover something on these 18 acres that I did not know I had before—something to feel happy about. And then, you know, whatever discoveries I make here are all mine—mine and God's. I know he likes to see me happy with them, for I can feel the sunshine of his love while I am engaged in this work. A great many farmers are deterred from making improvements, and developing the resources of their own possessions, by thinking that it *won't pay*. My friends, does it pay to sit still, and let your horses stand idle in the stable? I would not advise hiring help for work that is uncertain in its results; but I would advise employing your time, and the time of your team, in place of letting them stand idle. You can do this, and not be out of pocket, and a penny saved is a penny earned.

Now, what is there almost every one who reads GLEANINGS can do, with a reasonable chance of having it pay, and that he can do without expending money? What business can *everybody* go into without capital? You see, I begin to talk something like these advertisements in the papers that promise ever so much for nothing. Why, my friends, it seems to me the answer to this great problem is that, instead of going around to factories and shops for a job, we just go straight to God and take up the same kind of work that he first gave Adam and Eve, when he told them to earn their bread by the sweat of their face. Go to old mother Earth, and get a job of her. If you like keeping stock, go and take better care of the stock you have already got, instead of sitting idle. If

you are not the possessor of even a chicken, may be it will take some money to get a start; but God will give you the opportunity of earning money for this start, if you are in earnest. You can do almost all the work needed in raising poultry during these spare evenings, when you would be otherwise loafing or doing worse. You can get some dirt, and start some plants right off now, when this number reaches you; and you can buy seeds at five cents a paper, or even three cents, of some of the seedsmen. You can find boards around home to make boxes of, to hold the dirt; and the boxes can be in the window, if you have not any better place.

Neighbor H. once raised a wonderful crop of melons by sowing the seeds in boxes made of newspapers, and setting them in the window. When the weather permitted him to work in the ground outside, he set the paper box between two bricks, laid a pane of glass across them, then banked the dirt around them. The pane of glass was very easily slipped off or on, as the weather permitted, and he had melons about the time we get them from the South. Enormous prices are paid for extra-early fruits and vegetables, and you can make preparations for these in the way above indicated, and the work may employ all your evenings from now till time to work outdoors. I know some have complained that the markets are overstocked—their stuff won't sell. Well, if it does not sell, use it yourself. There are methods now of preserving and keeping almost every thing heretofore considered perishable. We have celery now on our table as nice as when first taken from the ground in the fall. All you have to do is to plant it in the ground in your cellar.

A great many people say they have not the faculty of making things grow—every thing dies they undertake to fuss with. My friends, you can learn to become an expert in making things grow, and the catalogues that are given away freely to everybody nowadays will give you all the instruction you need. A few months ago I hired an expert market gardener—at least, he was recommended as such. He killed my choicest strawberries by the lavish way in which he used guano, and killed my potatoes (as well as the bugs) by the lavish way in which he used Paris green. In fact, he used almost every thing much as the "hired help" uses butter and sugar when she goes into the kitchen. Then one of our own boys took a fancy to the greenhouse, and he has commenced cautiously, feeling his way with plants, seeds, fertilizers, and different kinds of soil; and now he is getting a good many things so much at his fingers' ends that he begins to succeed with every thing he undertakes, and he has had only a few months' practice. One who loves God, and loves these tiny seeds as they burst forth from their earthy covering, will be almost sure to succeed. Even if you fail, if you work as I have advised, you are out of pocket so little that you may almost say nothing. If what you raise won't sell, use it yourself; and though every thing is low, if we stop outgoes we shall be far better employed than in doing nothing.

My remedy for unemployed people will be to get them to go out of the cities into the country, and raise their own food; and rather than have so many thousands out of employment, I should say raise your own clothing as well. Go back to old times until there is a "let-up" on this crowding on to manufacturers. Very likely it would not pay one who raised food products to raise sheep, and spin and weave, as we used to do; and, in fact, clothing is so very cheap now—at least, comfortable and decent clothing is, that there can be little need of it. I know that people say, over and over again, that the stuff won't sell. To be sure, it won't, unless you sell it. Neither will potatoes dig themselves nor cook themselves. God does his part, and you are to do your part. When you have plants and vegetables ready for market, sell them as we do honey. Don't be above peddling them out among your neighbors; and when you go, if possible *take orders*. Pretty soon, instead of having to peddle you will simply have to *deliver* your stuff, and that is not unpleasant at all. When you have been "faithful in few things" for only a very little while (comparatively), customers will come to your doors and purchase. At a horticultural meeting, a member said recently that the best customers he had for strawberries were among the *farmers*, and in the small villages.

I know many will reject the course I have pointed out. Very well, friends. If you have something better to do than what I have indicated, by all means do it. But do not say again you could not find any thing to do. You can not be trusting God while doing nothing. You may find fault, and say, "How is a box of cabbage-plants and such like stuff going to support a family?" But, my friends, how is *doing nothing* going to support a family? The course I have recommended will show that you are willing to do your part, and being busy in some honest employment is a recommend to anybody who wants hired help. A business man seldom wants to employ idle people, as he has learned by past experience that it does not pay.

In connection with the thought that I have given in the fore part of my article, the statement was made that *many thousands* were fed or relieved from suffering at public expense; and I believe the statement was made that those receiving charity in the city of *Cleveland alone* were so great in number that it was safe to say that one individual in *fifteen* was a *pauper*. I am really afraid the aid given has, a great many times, done harm by encouraging people in idleness. It encourages them in declaring they won't do any work unless they receive a certain sum. This, to me, would be an indication in the outset that the one seeking work was wrong at heart. Better, a *thousand times better*, to work for 12½ cents a day, than to be the recipient of public charity.

A part of my talk to-day is not very bright and cheering; but now in closing I want to say something about a really bright, vivid trust in God; and I do not know any better way for any individual to show his trust in God than by showing a willingness to take

up any sort of duty, rather than idleness. Paul said he was ready not only to be bound, but to die for the Lord Jesus. We are not called upon to do Paul's work, many of us; but God does call upon us to raise plants, make garden, collect manure, peddle strawberries, and a thousand other such like duties, for the sake of the Lord Jesus Christ. Are we ready to do it? Are we ready to prove our trust in him in just this way?

A few days ago one of our evening meetings was concluded with the last verse of a little hymn. This hymn was a favorite of Rowland Hill, and he repeated it, or attempted to repeat it, with his dying breath. It is this:

And when I'm to die,
Receive me, I'll cry,
For Jesus has loved me, I can not tell why;
But this I can find,
We two are so joined,
That he'll not be in glory and leave me behind.

You notice, friends, the expression, "For Jesus has loved me." Our good friend was sure of that, even though he recognized that there was little about him that seemed lovable. And still further, his friendship and companionship with the Savior had been such during life that he had perfect assurance that the Savior would never leave him. Perhaps I can make it plainer by a little incident.

Although it was a cold, wintry day, almost down to zero, Huber begged so earnestly to go down to the pond that mamma bundled him up in his little sled, and I drew him off through the cold white expanse of snow. When I got down there I discovered the "Jersey bossy" could not get any water, and it was some distance to where I could find an ax to cut a hole through the ice. I explained to him what I wanted him to do, and that I would be back after awhile. He looked up at me with his blue eyes; and although he could not understand much that I said to him, he gave me to understand that he would stay until I came back. There he sat, a little speck, all alone by himself, away off in the field, just a baby. Do you think the idea ever entered his head that his papa might leave him there to starve and freeze, and never come back at all? Not a bit of it. All through the brief span of his little life, there had been such a friendship between him and his papa, that he knew, without being told, no power on earth could induce papa to leave him. Even if I *was* gone a very long time, his childish faith would never waver. He could not plead any merit of his own. There was no particular *reason* why his papa should think more of him than the Jersey cow, ponds, sunshine, or all this world could offer, yet in his baby heart he knew it was so; and therefore, even though I was gone a much longer time than I expected to be, he sat quietly and patiently, gazing off on the white sea one way and then another; and pretty soon, when he got weary of sitting still, he just lopped his little head forward, and—went to sleep. Why shouldn't he? He was so bundled up that he could not get out of the sled if he tried; and even if he did get out, he would make matters a great deal worse. If he should scream ever so loud, nobody could hear him. The *only*

thing to do was to trust his papa, and wait till he came back in his own good time; for he knew it was an utter *impossibility* that he should ever leave him where there was a chance of harm. Do you see the figure? "Consider the lilies, how they grow." When you are doing all you can, and all that God can in reason expect you to do, why should you doubt him, or lose faith?

Fear not, little flock; for it is your Father's good pleasure to give you the kingdom.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER.
MEDINA, O.

TERMS: \$1.00 PER YEAR, POST-PAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, FEB. 15, 1885.

Behold, I give unto you power to tread on serpents and scorpions, and over all the power of the enemy, and nothing shall by any means hurt you. LUKE 10:19.

A BOOK ON SILK CULTURE FOR TEN CENTS.

We have one more book for the ten-cent library, and this time it is on silk culture. By mail, one cent more.

OUR BEES AT THIS DATE, FEB. 6.

DURING the recent warm spell, our apiarist carefully examined our 138 colonies, and found them all in good trim except one. This one had almost entirely natural stores last fall, so it was fed very little sugar syrup. Almost all the rest were fed quite heavily.

DECREASE IN THE RATES OF FREIGHT.

THERE has one good thing resulted from the general depression in business; and that is, that the railroads have, most of them, given us better rates of freight. Our friends will discover that, as a rule, freights are much less, and the late issues of our price list make mention of the reductions we have secured.

VERY LONG LETTERS.

I AM sorry to say it, but a very large heap of long letters is piled up waiting for me to get time to read them, and it will be nothing strange if I never get time in the world. Very likely some things of much value are among them, but I do not know that it can be helped, unless you come to the point at once, and make your communications brief.

WHITE-POPLAR SECTIONS, DOVETAILED ALL AROUND.

WE have been at some expense in getting the celebrated white-poplar lumber, and are now prepared to furnish sandpapered sections, equal to those made anywhere, we think, at the following prices: 100, \$6.00; five or more thousand, \$5.75; and ten or more thousand, \$5.50. Sections made so that 7 fill a foot of space, same price as above. If made of husswood instead of poplar, 50 cts. per 1000 less. Packed in boxes of 500 each. Less than 500, 3/4 of a cent each.

DISCOUNTS FOR THE REST OF FEBRUARY.

AS we have recently purchased quite a large lot of wax, at prices almost as low as it was offered in the fall, we will continue our discount of ten per cent on foundation until March 1st, and may be longer. Although sections are moving off quite rapidly, we have concluded to extend the discounts we have been giving on them, and on foundation mills also, until our next issue.

ADVANCE IN THE PRICE OF PEA-VINE, OR MAMMOTH RED CLOVER.

IT seems to me there is some difficulty in getting the genuine. On one occasion we sent to a noted seedsman for seed for a couple of acres; but when it came up it was common red clover. We have some that we know to be genuine, because it was raised by Neighbor H.; but instead of the prices in our price list, read \$8.00 per bushel; \$2.25 per peck, or 20 cts. per lb. If wanted by mail, 18 cts. extra for postage.

NICE HONEY AT A LOW PRICE, IN CONVENIENT PACKAGES.

IN friend Heddon's circular and price list, we noticed honey in 50-lb. kegs, at \$4.00 per keg. As the price is low, I, just to see what it is like, ordered a keg. The honey emptied out 53 lbs. 12 oz., and proves to be a very nice article of remarkably fine clover honey. Friend H. says in his price list he has 400 lbs.; and if it is not already gone, it ought to go very quickly at the price quoted. We have been a little prejudiced against kegs for extracted honey; but this came to hand perfectly clean, and without a bit of leakage. It began to leak some, however, after it had stood in a warm room three or four days.

SELLING INTOXICATING LIQUORS AT OUR STATE AND COUNTY FAIRS.

WE are pleased to extract the following from the *Farm and Fireside*:

The Annual Agricultural Convention of Ohio, held in Columbus on the 11th of January, resolved by a vote of 1614 yeas to two, out of sixty-one counties represented, "That the time has arrived when the public sentiment of the State demands that the State and County Boards of Agriculture should exclude from their grounds all persons and meetings."

In the whole convention, consisting of sixty-one voting delegates and a large number of non-voting members, but three yeas were heard in opposition to the resolution, and their opposition was made only on technical grounds; while of those favoring the resolution, several would be on their feet at once, claiming recognition of the speaker, in order to give its passage. The whole scene was a note making an Ohio farmer more than ever proud of his State and of his calling.

Not only an Ohio farmer, but it seems to me every loyal citizen residing in Ohio ought to feel proud of the stand just taken. May God grant that this regulation shall never be reversed.

HEDDON'S SLATED HONEY-BOARDS.

AFTER my remarks on page 98, last issue, had gone to print, it occurred to me that E. Kretschmer, of Coburg, Iowa, did, a great many years ago, have an arrangement for a sort of honey-board with slats to break the spaces made by the brood-frames; and as soon as the article in question met the eyes of friend K., he sent me an article giving the details of a patent, granted July 23, 1868. The article is too long for publication, and, in fact, I do not know that it matters much after all, only it is pretty evident that the device alluded to is not new. At present, GLEANINGS will not contain one-fourth of the matter sent in for publication. The trouble is, so many of the brethren make long stories of what ought to be told in a few words. We are willing to give space to matters of general importance

to the greater part of our readers, but we can not publish long letters that are likely to interest only a few, comparatively. Any one can have friend K.'s communication who cares to pay the postage on it.

UNTESTED QUEENS IN FEBRUARY AND MARCH.

Who is there among our friends in the South that are able to ship untested queens now? Let him speak out, and we will give him a free ad.

DON'T forget the bee-keepers' meeting at the Exposition in New Orleans on Tuesday, Wednesday, and Thursday, Feb. 24, 25, and 26. I shall be on hand the second day, nothing preventing.

THE EXPOSITION AND SUNDAY.

I AM informed that every exhibitor has the privilege of covering up his goods so that they can not be seen on the Sabbath-day, if he chooses. If this is the case, the matter is in the hands of the exhibitors to a considerable extent, and we may hope that Sunday exhibitions will be found so unprofitable that they will be discontinued.

A BOOK ON CARP CULTURE.

I HAVE completed arrangements with Milton P. Pierce, Secretary of the American Carp-Cultural Association, for writing me a book on carp culture. Mr. Pierce is perhaps the best authority we have on the subject in the United States, and perhaps the best in the world. The book will be fully illustrated, and the price will not exceed 50 cts., and probably not over 35. Further particulars will be given later.

OUR REVERSIBLE FRAMES.

THE machine for making our reversible frames is not yet completed, and we can not very well send out good samples till the machine is finished; that is, there are so many orders for them that they would cost a great deal more than we get for them, made by hand, and they wouldn't be very nice either. The engraver is at work on a cut, but we are obliged to go to press without it. Devices for reversing are coming in by the score; but a great many of them are only repetitions of what have been figured and described in our back numbers. Before you waste much time in inventing, dear friends, it will be well to post yourselves in regard to what has been done already.

OLD BONES.

YES, what do you do with them around your house? We have just commenced saving all of ours, and in the adjoining town there is a mill where they grind them up for poultry, and for fertilizing purposes. We just got a bag full, and I thought it looked a little coarse for plants; but I mixed in some with a box of nice soil, sprinkled on some radish seed, then a little more bone meal, and over all some dried moss rubbed up fine, and sifted on the seeds with a sieve. The whole was placed in the greenhouse, in the sun. In just four days the seeds were pushing the moss out of the way, to get up, and the bone meal had, in that short time, become so decomposed that it looked like a mass of mold, and the radish roots were pushing all in through it. Our bone-mill pays \$16.00 per ton for any sort of old bones. Chickens will eat them when ground up, as greedily as if they were coarsely broken grains of corn. Save the bones.

MOORE'S CRATE FOR HOLDING SECTIONS.

AS quite a good many seem to prefer this arrangement for placing sections over the hive, we have ar-

ranged machinery for making them at a low price. The only important thing in their construction is to have the partition-boards spaced so the $4\frac{1}{4}$ x $4\frac{1}{4}$ sections will exactly fit. To do this we have a saw-arbor arranged with thick saws, to cut grooves for the partitions to slide into. As the whole 5 grooves are cut at one operation, the crate is made very cheaply. The price of a single crate, nailed up, will be 20 cts.; 10 crates, \$1.50; 10, \$16.00, to which must be added the price of crating. Price of Moore's crate in the flat, singly, 15 cts.; 10, \$1.35; 100, \$12.50. These prices include the necessary strips of tin, and nails for nailing them up. An engraving of one of these crates will be given in our next issue. One especial advantage these have over the crate we have been using is, that it holds each section exactly square, and when filled with honey they come out all ready to go into the shipping-case, square and snug. These crates will go *inside* of a Simplicity hive.

REVERSIBLE FRAMES.

FRIEND HOWES, whose reversible device has been twice illustrated in GLEANINGS, claims that friend Heddon's arrangement is an infringement on his invention. Now, perhaps I am not the one to decide this matter, but this is certain: Although I examined Howes' device carefully when it was first submitted, and have studied a great deal on the subject, it never occurred to me to unite the two supporting arms by an extra top-bar, until I saw it in Heddon's article in the *A. B. J.* So far as I know, friend Howes was the first one to suggest pivoting the device to the center of the end-bar of the frame; but it seems to me, that as soon as a device should be called for, for reversible frames, this would be one of the first things to occur to almost anybody. If it did not occur to anybody until it occurred to friend Howes, very likely the idea would be patentable. Now, in case he does get it patented, as to whether friend Heddon's plan infringes or no, it seems to me lawyers might argue the matter a long while, and never settle it even then. We have never used the arrangement, and I do not think now we ever shall.

GILT-EDGE MEN AND WOMEN.

MAY be I have talked about this before, but something tells me it won't do any hurt to talk some more about it. In that big index-book to our ledger, that I told you about (the one that indexes a quarter of a million of people in our business transactions), we are obliged to record character, and grade character, as it were, and the grading runs all the way up from the man who coolly repudiates a fair and square promise, to those who are so careful of their commercial standing that they would almost pay something they did not owe, rather than have appearances against them. Once in a while we find a phase of humanity so fair and unselfish that I told the girls we wanted some way to indicate such men in that big index, and I proposed that we should call them "gilt-edge." A few months ago we changed the table giving the price of our foundation-mills, to a smaller-sized type, to give more room. One of our best men did it, who almost never makes a mistake; but this time he got the wrong figure, and made the price of a \$40.00 mill only \$30.00. Before it was discovered, some price lists had slipped off. A customer got one, and, not suspecting any mistake, sent \$30.00 for the mill. It was a fair and square bargain, so we sent it along, but said that the price was a misprint. He replied

promptly that we should charge him the proper price, and it would be all right. He did not want any thing of anybody for less than it ought to be, on account of a mistake. We have marked him "gilt-edge;" and what ever happens in future, we know the man means to be right, and that we shall never run any risk in trying to accommodate him to whatever he wants.

TAKING MEASUREMENTS.

NEVER use a rule or square, if you can possibly avoid it. Have a lot of slim sticks; and when you want the dimensions of something that needs to be very accurate, cut off a stick just right. If you want two dimensions, cut a notch in the stick for the second one. If the dimension is long, say the size of a door, lay two sticks together, slide one along the other until it just fits the opening, and tack them with a couple of slender nails, and you have it to a dot, without the trouble of cutting a stick. When I am hurried and worried, rules that shut up are a bother. When I want them open they are always shut up; and when I get them straightened out, they double up and flop around. On our 3-cent counter we have one-foot rules made without joints. This has a knife edge, as you will see by the cut below. It is also graduated and numbered.

OUR THREE-CENT ONE-FOOT RULE FOR SCHOOL CHILDREN.

I find these very handy, and I do not know but I would give a dollar for one, if it could not be bought cheaper. I keep one on my desk, and when I want it to measure any thing, I grasp it by the end where the figure 12 is. Now place the other end, where it says 1 inch, on the article to be measured, and you can read the dimensions exactly, in an instant. Besides the rule, I also have a yard-stick made in the same way. These are on the 5-cent counter. I always pick this up by the end that is marked 36 in., and place the other end on the article, and then I can read off the inches and fractions, without much chance of a blunder. These two rules, the one-foot and the three-foot, have proved to be so very convenient that I am going to have some on knobs just under the edge of my desk, with the end to grasp hold of sticking out so I can get hold of it in a second. The one-foot rule can be mailed for 2 cts. extra. The yard-stick can be mailed for 5 cts. extra, but I can not guarantee the latter against breaking in the mails.

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or \$2.00 per year.

\$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or \$2.00 per year.

Those whose names appear below agree to furnish Italian queens for \$1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen is reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with * use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for \$1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

GEORGE GRIMM, Of Jefferson, Wisconsin, Will Sell

300 TO 400

COLONIES OF BEES IN THE EIGHT-FRAME LANGSTROTH HIVE, AT THE FOLLOWING PRICES:

Pure Italians, 1 to 5 colonies, at	\$6.50
" " 5 to 20 "	6.00
" " 20 or more "	5.75
Hybrid Italians, 1 to 5 "	5.75
" " 5 to 20 "	5.25
" " 20 or more "	5.00

Terms and conditions as follows: Orders will be booked only when accompanied by the cash, and will be filled in their proper turn. I will ship some time in the month of May, and the exact date must be left to my discretion, to be governed by the circumstances and the weather. I will notify before shipment. Will guarantee safe arrival at last express station, and will guarantee satisfaction.

UNTESTED QUEENS IN MARCH.

I should be pleased to get some orders for untested queens during March and after.

M. THROCKMORTON,

Houston, Harris Co., Texas.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is often times quite an accommodation to those who can not afford higher priced ones.

I have 5 pure hybrids (Italian), and 8 pure black queens, to be removed about April 1. Hybrids, 60c, and blacks, 30c each, prepaid by mail, and safe delivery guaranteed.

NOTES FROM THE BANNER APIARY.

NO. 63.

THE HEDDON FIXTURES AND SYSTEM.

NOW that this subject is up for discussion we may as well stick to it until it is finished. You, friend Root, in your report of the Mich. State Convention, page 81, say that, while we were visiting the college apiary, you noticed that the crates and honey-boards, made upon the Heddon plan, were covered with bits of comb and propolis; but you neglect or forgot to state what *my* eyes instantly detected, and what Prof. Cook mentioned; viz., the cases were not properly constructed; the spaces between them were not the right size. Since I have been using the Heddon case and honey-board I have experimented some to determine what sized bee-space would give the best satisfaction, and I have found it to be 5-16. If this distance is increased very much, brace-combs are the result; if decreased, propolis is the penalty.

I am glad to see you admit, at last, that the Heddon hive-cover will not warp. Now in regard to the "twisting" feature, I have used 125 of the covers, and only two of them have caused any trouble by twisting; and, if one cares to take the trouble, this can be remedied by taking off the end cleats and using the remaining board for making a bottom-board. You say, "The cover has no place, but stays just where you lay it." I do not see that this is an objection; perhaps you did not mean it as such. It is just as easy to lay a simple flat board over a box, the upper edges of which are plain and flat, as it is to put in place a cover with a rim around it, the rim being beveled to fit the beveled edges of the box or hive; and so far as the staying

in place is concerned, the wind has yet to even displace the first cover of the Heddon style for me; what more can you ask?

In regard to taking out sections one at a time, versus a whole case at a time (see J. W. Porter's article, page 123), I would say that I should not take out sections one at a time as fast as finished, even if their places *could* be filled with empty sections, and no bulging result. When tiering up is practiced, the finished sections are always in the top case, and there is not that travel over them that there is in the lower cases, and they can remain until the whole case is finished, and not one of the combs show any stain. However, I do not always leave a case upon the hive until every section is finished. If there is a section in each corner unfinished, I do not usually wait for them to be finished, but take off the case, "whack" out the sections, crate the finished ones, and set the three or four unfinished ones into an empty case. When the case becomes filled with nearly finished sections it is put upon some hive. But to show how nearly I sometimes allow the sections to be finished before removing them, I will mention that, from the first 1000 lbs. removed last season (that sent to A. C. Kendel, and you will remember how he praised it, and pronounced it the best lot of the season), there was only *one* case of unfinished sections (28) to put back on the hives.

In raising honey I fail to see why, as Mr. Porter says, "We have frequent need to get into the brood-chamber;" and, honey-boards or no honey-boards, I see no use for a "flexible quilt."

The Wilkins sisters, unless I am mistaken, and I think I am not, do not allow the bees to have access to the outside of the sections; *i. e.*, they have the Doolittle system, as mentioned, and, with that sys-

tem, the sections are placed in wide frames, and the propolis is placed where the edges of the sections come in contact with each other and with the wide frames. I think that, in a majority of localities, bees do not propolize smooth surfaces unless they are nearly or quite in contact.

J. W. Harkness, page 128, admits that an 8-frame hive is preferable to a 10-frame one, but objects to a change, on the ground of cost. Bee-keeping is making rapid strides, and changes are necessary; but let no one change until he is satisfied that it is best for him to do so. I changed both hives and frames when I had 100 hives, and have been thankful ever since; but it does not follow that *everybody* must make the same change.

W. Z. HUTCHINSON, 68-34.

Rogersville, Genesee Co., Mich.

Thanks, friend H., for the additional light you throw on many points of the Heddon fixtures and system. As soon as you mentioned it I did remember that Prof. Cook made the remark that his cases were not made right, but it did not occur to me that this fault in the make was the cause of the propolis and bits of comb on the sections. You say none of your covers have been blown off; but perhaps there has nothing happened in your vicinity to "raise a breeze," since you adopted the Heddon system, friend H. The system itself seems to be raising something of a "breeze" just now, any way; but I hope nothing but good will be the result of the "blow."

HIVE-COVERS, ETC.

A "REVERSIBLE" COVER, AS WELL AS REVERSIBLE FRAMES.

NOW, Bro. Root, it is quite according to human nature that this odd-looking cover of mine should fail to suit you. You nowhere mention that it is *reversible*. I have used it for four or five years. The cut that did not show it, was a very old one. The cover I sent you was a cull, one in a hundred. I wrote so, I think, when I shipped. I was unexpectedly bought out faster than I could get them painted ahead. This style of cleating (see cut on page 121) not only serves to give us a strong well-stayed cover, but a reversible cover that always has a projection of $\frac{3}{4}$ inch *above*, so that when the shade-board is laid on, this ever-present space cuts off direct communication of heat. There is no system of shading that suits me as well as this adjustable shade-board. Now, if these covers should "wind," or twist, a chip laid on one of the high corners would touch the shade-board, and its weight would take the "wind" out of the cover at once. I think you will believe us, when we tell you that this warping or winding matter gives us no trouble at all. Now, I don't like the Simplicity style of cover, for I am greatly opposed to the use of any kind of a cloth for summer; and a telescoping cover, i. e., one that has any notches or ledges or rabbets to fit down into any thing, are not fit to cover up bees with. I have no objection to them for an outer or second cover, but I want but one cover to my hives, and then a shade-board to put on or take off, as the heat of the season indicates. I think this a grand style of cover; but as soon as it becomes popular, won't there be some one to come forward and claim that it is old?

THE SINK HONEY-BOARD.

The honey-board is objected to by J. W. Porter, on page 124. Bro. Porter all the time talks of the bungling, obstructive honey-boards of old. I want him to just try the sink skeleton board, an accurate cut of which appeared on page 121. If he does, I feel sure he will never discard it. Nearly every year, for three seasons past, the demand for these boards has so increased, and that, too, so much beyond my expectations, that I have found myself short, and had to rob my own apiary, and in this way I have had about half of my colonies with and half without the honey-boards. I have enjoined my students to keep close watch, and see if the boards were any detriment to the ready acceptance of the sections. Every time the word comes, "*Not at all.*" The question of the "bees readily entering the surplus department" now sounds like an echo of the more ignorant past. I would not use a system one moment that in the least retarded the bees from going to work in the surplus department, as soon as there was any outside condition to make such work *possible*. Just here, honey comes so fast from clover and basswood, that no removal of parts of cases or sections is practical. It is best to remove the surplus, by cases. Not all localities are like this one, perhaps. Honey-boards were discarded because they were not properly constructed. They are now again recommended, because they are now made in a practical manner. If Mr. Kretschmer invented my honey-board years ago, why did it die? Was it in practical shape? I never heard of it. In what place can I find a cut or description of it, that is also old? Was it a sink honey-board? that is, was there a bee-space in the honey-board itself? Won't this turn out like the Moore rack? Honorarily, the right belongs to the one who puts a device forward, thus benefiting the fraternity.

HOWES' REVERSIBLE FRAME, AND MORAL PATENTS.

Now, Bro. Howes thinks I am an infringer upon one principle in his reversible frame. Well, perhaps I am. If bee-keepers so decide I will step down and out, and my frame may lie dead till Bro. Howes and his adherents find out that my inventions in my frames put his principle in much better shape than he has it, when he can come and compromise with me; for in that case neither one could make my style of frame. It needs no patent, *so far as I am concerned*; no costs. I can abide by the decision of an unpaid as well as by a paid judge or jury. I advise Bro. Howes not to patent his device,

1. Because it is not worth a patent.
2. Some other device, patented or unpatented, will come up and kill his device, and the money he spent in patenting.

3. It will be shown that the hinge principle is older with another than with Mr. Howes.

Now, if my third statement prove correct, Mr. Howes would have no advantage from his patent. But should it prove incorrect, he will have the advantage of the moral sense of the honest men of our brotherhood, and I will do all I can to defend him in his right to that hinge, as he was the first to make it *public*, and *honorarily* it is his.

Now, brother bee-keepers, do I infringe? If so, say so, and I will abide by your decision. Bro. Howes shall be treated by me as I wish to be treated by him and all others. I tell you, I have little faith in trying to annul one's inventions by rooting up some old dead fixture that shows the

same principles, or part of them, in an impractical form. The question still wells up, Why did it die? For months or years it has lain a corpse, good for nothing, except to be dug up to cheat some one out of his honest earnings. The patent decisions are beginning to look at this matter also. Men that will stand up before the solemn duties of a court of justice, and swear falsely, are too numerous for safety.

JAMES HEDDON.

Dowagiac, Mich.

Now, friend H., why didn't you tell us that your cover was meant to be reversible? I looked at it and looked at it, and wondered what possessed you to get any thing up so awkward looking, without any point to it. But had you just hinted "reversible," then it would have been all clear. Then, again, that ingenious device for holding a shading-board; if you have ever spoken of that before, I had forgotten it. I supposed you put a great rock on these boards piled up on top of your hives, to keep the wind from blowing them off; and very likely great rocks are plentiful in Michigan, even if they are not here in Medina. Yes, sir, I agree with you that laying a chip on the upper corner, and laying on a shading-board, will take out the "wind." It seems to me, that, with the business you are doing, you ought not to use cuts that do not show things as they are; and besides, why not explain more in your own price list of articles what the things you use are intended for? In regard to friend Kretschmer's invention, it was described in his book, and to some extent in journals and price lists. As it would take me a good deal of time to hunt it up, I just turn the whole matter over to friend K., who, I suppose, can give you the points readily.

WHAT ONE OF OUR BEE-KEEPERS DID IN THE WAY OF RAISING POTATOES.

OVER 1600 LBS. OF POTATOES FROM ONE POUND,
IN ONE YEAR.

PERHAPS many of the friends have noticed reports going around, in regard to potatoes, and large yields secured by the prizes offered by a company who has a special fertilizer for sale. Noticing that one of the successful potato-growers lived in the neighboring town of Akron, I wrote to him, to inquire about it, and I was a good deal pleased to know that he is no other than one of our bee-men. Below is his letter, telling us how he did it:

A. I. Root:—Your favor of Jan. 25th came duly to hand, contents noted, and in reply would say:

On the 5th of April a pound of whole Dakota Red potatoes (not eyes alone) were cut and planted in earth under glass, with artificial heat. As the sprouts appeared above ground they were pulled off as you would sweet-potato sprouts, and potted. As the detached sprouts grew, cuttings were made and rooted, continuing the above process until as late in the season as I thought I could make cuttings and have them produce potatoes. They were then planted in what I would call a clayey loam, but so near the turning-point that some people call it a sandy loam, that had been thoroughly worked and

fertilized with a fertilizer purchased of the Bradley Fertilizer Co., Rochester, N. Y., and sown broadcast at the rate of 1000 lbs. per acre. That was the only fertilizer used. They were worked flat or level with a horse cultivator and hand hoe. With a potato that is good to yield, a good fertilizer, good soil, and a good deal of good care, one may expect good results.

CHAS. C. MILLER.

Akron, Ohio, Feb. 9, 1885.

The above potato, it seems, is attracting considerable attention just now. In response to whether friend M. had any potatoes for sale to plant this season, he sent us the advertisement you will find on another page. We extract the following description of the Dakota Red potato from Sibley's catalogue for 1885:

Dakota Red.—New; a large, very handsome, long, wedge-shaped potato; thrives well on both sand and clay soils. Western New-York Potato-Growers, who have tried it, say it is the best that ever grew. It tastes much like the good old *Peachblow*; does not shrink in cooking; is solid, mealy, and fine grained; the outside skin peels off in boiling, and leaves the inside intact, not crumbling to pieces; eyes irregular, some smooth, some deep, but few in number; skin firm, reddish flesh-colored; flesh white, of fine flavor; vine stocky, and keeps through drought by reason of the roots growing deep into the soil.

I have taken pains to find what the fertilizer above mentioned costs, and the 1000 lbs. delivered at his station probably cost him less than \$20.00. Now, I do not know how much time friend M. occupied in this work, nor do I know how much ground he used. The number of pounds of potatoes he raised was 1677 5-7. Probably the expenses were not more than \$25.00 out, besides his labor. His crop of potatoes, if sold at the prices advertised, will bring him something like \$75.00, in round numbers.

One reason for giving this was to show what a wide-awake, enterprising, industrious man or woman may do in the line of work mapped out in *Homes* in our last issue. The Bradley Company paid him a premium of \$75.00 for his feat. Now, friends, we can get similar results from bees, poultry, and a dozen other things (I was going to say a hundred, and I guess it would not be far out of the way) by putting brains and hard work into it. While I think of it, our friend Terry, the great potato-grower of the State of Ohio, is now engaged in writing me a book on potato culture, which we expect to be forthcoming in a few weeks. The price will be moderate, and we expect it to be up to the times in every thing pertaining to potatoes.

D. A. JONES'S FRAME AND HIVE.

SOMETHING ABOUT THE KIND OF HIVES THAT OUR
CANADIAN FRIENDS USE FOR GETTING THE
TREMENDOUS CROPS OF HONEY THEY RE-
PORT NOW AND THEN.

SOME time ago Ernest reminded me that I was doing wrong in making no mention in the A B C book, price list, and GLEANINGS, of the hives preferred by friend D. A. Jones and his large class of pupils throughout Canada and other territory. I accordingly wrote for a sample frame, which we will show by an engraving

soon. This frame is peculiar in being about 11½ inches wide by 14 deep, outside measure. The extreme length of top-bar is 13 inches, and is a heavy V-shaped comb-guide, made of one piece of wood. This comb-guide is really a three-cornered piece of wood about ½ inch on the side, and forms shoulders to which the end-bars are nailed. The distance from shoulder to shoulder is 10½ inches, so 10½ inches is the width of the frame inside. The end-bars are ½ inch thick, and exactly 14 inches long. The bottom-bar is exactly 12 inches long, and has projecting points, which are almost a necessity for a frame so deep. These points strike the sides of the hive when putting a frame in place, preventing bees from being crushed. This bottom-bar is set edge-wise, and is very light, being only ½ inch by a little less than ½. Below is what friend Jones says in regard to it. Now, the following letter was not intended for publication; but it is so rare that we get any thing from friend Jones I am sure he will excuse me.

Friend Root:—Please accept our thanks for your kind offer, which is duly appreciated. I will have a frame built to size sent you. In marked catalogue which we forward you, you will find inside measurements of frame. There are now a great many thousand of these hives in use throughout Canada; in fact, I believe more of them than all others put together. There are hundreds manufacturing them besides myself. Out of orders received last year for 37 different sizes, 95 per cent of the whole amount sold was our size. We have no axes to grind in the frame or hive business, and would as soon make one kind as another, and adopt, could I secure better results; but after a trial of 14 years by the side of the shallow frames, the results were so much better that I could no longer resist the temptation of using them exclusively. When Mr. Langstroth visited me, accompanied by Judge Andrews, it would have done you good to see how readily father Langstroth could handle my frame, and he was so delighted with them that he asked me to construct him some hives that he might give them a trial; but they were never shipped him, on account of his sickness soon after.

You will observe that the bottom-bar projecting prevents the frame from touching the side of the hive in manipulation. This allows of greater rapidity in handling. One frame is laid on side or stood on end; no bees can be mashed, as the projections keep the frame bee-space above board.

If you do not issue your new book before the first or middle of April, I can give you some new improvements to put in it, in connection with bee culture—things of very great importance in wintering bees, the production of comb honey, improvement in sections, and a number of other valuable things which would perhaps add a little to its interest.

Some years ago I thought of making metal corners, and made a great number of devices, some of which I believe are not equaled yet. Although I did not take to the metal corners favorably, yet since reversible frames are receiving some attention, I believe that some of the simpler ones would be hard to beat. If you send us one of your latest improved, and should it not be superior to mine, I will then forward you a sample for your inspection, to manufacture, of course, should you desire to do so, and no hundred-dollar charge either.

Becton, Ont., Feb. 16, 1885.

D. A. JONES.

We send you a sample of our latest reversible frame, friend J., and I should be extremely happy to have suggestions from you before our next edition of the A B C goes to press. And by the way, friend J., we shall feel a little more free to trespass on your kind liberality if you would take some pay, in some shape or other, for the benefits you are continually conferring upon us.

FERTILIZING QUEENS.

PROF. COOK DISCUSSES THE PROBABILITIES OF A QUEEN BEING FERTILIZED BEFORE SHE EMERGES FROM THE CELL.

DEAR MR. EDITOR:—You ask my opinion about fertilization of queens after reading Mr. F. Cheshire's article in the *British Bee Journal*. I reply, that it is not at all changed. I have discussed this subject in a paper sent to New Orleans, to be read at the International Congress; but as I had not then seen the article in question, I will add a few words. Mr. Cheshire remarks truly, that the sperm-cells are quite mature before the drone-bee assumes the imago stage. If any one examine critically the reproductive or generative organs of the mature drone he will find that the testicles, or *testes*, are much smaller than they are in the pupa, or nymph. The reason for this is, that the sperm-cells have wandered, or migrated, having passed through the generative duct to the seminal sack, the *Vesiculæ seminales*. In this migration, mucous is added, and the cells are bunched, or massed, preparatory to coition. Thus massed they are passed down into the external organ, which, by a sort of turning wrong side out in copulation, deposits them in the oviduct of the queen, which clasps and forces them into the spermatheca.

Mr. Cheshire says that the sperm-cells are already active in the larva. He does not say whether in the mature or in the partially developed larva. I did not suppose they were active at all in the larva, but have found them so in the pupa. If they are active in the larva it must be when the latter is fully matured. That they are so at all, seems strange and exceptional. If they are active there can be little question but they are functionally perfect. The activity of the spermatozoa in all animals seems to be the test of vitality.

In the impregnation of the queen, millions of these sperm-cells are to be passed up the oviduct, and passed into the spermatheca. For this to be accomplished, the cells must be massed and forced, under the orgasm of the queen, along the oviduct, into the spermatheca. It is possible—hardly probable—that a few of these might wander along the channel, and find this destination in the case suggested, were the sperm-cells free, and the queen developed and ready for impregnation. All animals, insects included, have an age of so-called puberty, before which sexual instinct is absent, and impregnation impossible. I know in insects this is often early. I have seen butterflies in copulo soon after the female had emerged from the chrysalis, that her wings had not got dried. We know, however, that the queen leaves the cell days before the orgasm appears. To suppose, then, that putting an immature—in fact, a larval insect—into a cell where a queen is yet inchoate, and to suppose impregnation to occur, is, it appears to me, expecting more,

much more, than the law of probabilities will warrant. As Mr. Cheshire suggests, it is a field where we may experiment. Indeed, I have experimented, and with no sign of success. Had I seemed to meet success, I should have tried over and over again, for other explanation would have offered till all possible opportunity was destroyed. A. J. COOK.
Agricultural College, Mich.

REVERSIBLE FRAMES.

JUST WHERE THE MATTER STANDS NOW.

THE number of models received by mail is still almost as great as at our last issue. A great many of them are exactly what we picture below—the device described in our issue for Feb. 1, page 105. Well, after we had made about a hundred or so of these I did not feel satisfied with them; they did not stay up in place as I wanted them, and propolis would be apt to force the wires out of the wood where they go into the perforations of the end-bars.

FRAME-REVERSING DEVICE AS WE HAD IT ABOUT FEBRUARY FIRST.

While studying on this problem, meanwhile considering all devices that came in, I got a hint from one made of sheet iron, coming from friend C. H. Deane, Mortonville, Ky. Friend Deane uses a strip of heavy sheet iron, much like the Howes idea, only it was bent out so as to form a supporting arm in the shape of a loop made of the iron. The top piece of the loop extended over the top-bar of the frame perhaps half an inch; and when in place it rested on the top-bar with considerable pressure. This pressure kept it in place; and if the frames were not exactly accurate in their dimensions, there was spring enough to it so that it would adjust itself. The sheet-iron arm, however, I consider objectionable, because it will mash bees, or cut them in two where it rests on the metal rabbet, unless you use great care in handling. The wire loops shown in the cut above, I consider greatly preferable, and in the cut below you will see I have combined both.

ROOT'S FRAME-REVERSING DEVICE.

We put our frames together as you will notice, using bottom corners all around. But the same arrangement will work equally well on a nailed frame made without pro-

jecting arms to top-bars. I prefer the bottom corners, not only because they brace and strengthen the frame, but because, being made by machinery, they are absolutely alike, and always alike, no matter whether you bought them ten years ago or to-day. The reversing devices are also always alike, and can therefore be made so that they will come over the metal corner with a snap, the spring of the wire making it a pretty secure fixture. With the thumb-nail, however, the part that springs over the top-bar can be snapped off from the metal corner, then it swings over like the Howes device. Instead of being obliged to use a screw at the pivot where it turns, both wires are put through a quarter-inch hole, then turned over and clinched with a hammer. When put on just right, the points of the wires should describe a circle in the end-bar of the frame; that is, they press against the wood so as to make this circular scratch as they turn around, and the whole fixture is thus held closely and securely tight against the end-bar. The corner also possesses much greater strength than our old-style top corners, and the wires are so smooth that there is no danger of cutting the fingers. We have been shipping them several days, and are prepared now to fill all orders at the following prices:

Reversible frames in the flat, \$5.00 per 100, or \$15.00 per 1000; same already put up, \$1.00 per 100 extra. If they are ordered without hives in which to ship them, 25 cents per 100 extra, or fraction thereof, must be included for crating. Prices without wiring, and without the wood being pierced for wires, \$4.00 per 100, or \$35.00 per 1000, in the flat. A sample frame by mail will be 15 cts.; pair of wires by mail, 4 cts.; reversing corners, per 100, \$1.00; per 1000, \$7.50.

In making this corner I have infringed on the ideas of friends Howes and Deane; no others that I know of, although great numbers of devices made of wire have been sent in. I have written to friend Howes to know what I shall pay him for the privilege of using the pivot arrangement, providing he is the first inventor of said arrangement. I have also asked friend Deane to say how much I owe him for the idea he furnished, providing I continue using it. It is by no means certain that this is the best device that will be brought forth, but it pleases me the best of any thing I have seen or heard of.

BEE-KEEPERS' CONGRESS AT NEW ORLEANS.

NOTES BY THE WAY.

WE are just waiting for the train. I explained to Huber as well as I could that papa was going away off on the cars, for a good many days. He laughed, and began to jump up and down, as he does over any piece of intelligence that papa gives him; but when papa kissed them good-by all around, finishing up with his babyship, his little lips drew up, and he couldn't keep back the tears, and papa couldn't either. Oh dear! I do not want to go away from home at all. I love

my home, the factory, the greenhouse, the carp pond, and all the things.

ON THE WING.

It is 10 o'clock, and we are flying over the frozen landscape. The morning sun pours down a flood of light. You remember how I told you I had been thanking God lately for the sunshine. As the fields and towns fly past us, this wealth of sunshine comes out as it never did before. Of course, it does not even thaw the snow where we are now; for where we are it is still below zero. My heart bounds at the thought that at the rate we are speeding southward this beautiful panorama will soon change to one of spring time and verdure. Of course, the creeks and rivers we pass are all solid, and many of them form beautiful pathways for children, and for cattle and other farm stock; and, by the way, I notice cattle hunting low places, and pawing in vain for water. Is that the case with any of your stock, my friends? Remember our dumb friends. The sleighing is beautiful, and the hard level surface which the roads present is very pleasing. It is seldom that this portion of Ohio has enjoyed such sleighing as it has had for five or six weeks past.

2 o'clock P. M.—The snow is beginning to disappear, and the streams are uncovered. The sight of the babbling brooks is refreshing, after the scenery has been so long all ice-bound. I am enjoying my ride amazingly; and as my mind has been free from business cares, I have just studied out a great invention—or, rather, it came of itself. I will tell you about it some day. We are in the neighborhood of Springfield, Ohio.

REPORTS DISCOURAGING.

OUR bees are all dead—died with cholera. We noticed before cold weather set in that one hive had it, and we carried it away from the others. We had four hives; have the hives yet, for that matter. We were going to have at least four swarms, then I was going to send for the rest of your A B C book (I have the first part), and for GLEANINGS; but that is all gone. I write to ask you if you will please tell me what I can do with the honey and comb and hives. They smell very offensive. Will the hives give it to other bees? We feel worse about our bees, because our neighbor's bees that received no care are doing well. They said they did not care whether they lived or not. Could we have caused the bees to get the disease in our working with them? We wanted to learn about them.

AGNES HUDDLESON.

Victor, Iowa, Feb. 17, 1885.

I am afraid, my friend, you have packed your bees too close, and this would be the reason why the bees are all right that had no care. Shut up your hives so no robber-bees can get in, and in May or June give these offensive combs, one at a time, to strong colonies, and they will fix them in no time. When opportunity offers, it would be a good plan to brush out the dead bees, and brush off the combs as well as you can conveniently. Put the dead bees on your compost heap, and they will probably be worth something. The worse they smell the more

they will be worth for manure. I would not give up at one defeat, if I were you. If your neighbor's bees lived without *any care* it is pretty certain that your method of management has been at fault in some respect.

CAN'T KEEP BEES WHERE IT IS 30 BELOW ZERO.

I can't keep bees through winter in this locality, where the thermometer is 30° below zero. I started in winter with 36 colonies; lost 26; 10 alive now. There are now 250 full frames of combs. I am at a loss to know what to do with all of those empty hives and combs before the hot season sets in. I want you to advise some plan for me to get bees in them early in the season. The most of my bees died with plenty of honey in the hive.

W. RIGGEN.

North Salem, Ind., Feb. 7, 1885.

Friend R., if you have the low temperature you mention, continuously for several weeks, I would try wintering the bees in a cellar. You know this is quite extensively done now in many localities.

OUR FOUR-PIECE-SECTION MACHINE.

SOMETHING FURTHER IN REGARD TO IT.

BELOW we give to our readers an engraving of the four-piece-section machine we spoke of in GLEANINGS of Jan. 15. It works with perfect satisfaction, turning out as smooth and nice a section as you will find in the market. Owing to the improvements we have recently made on this machine, we can not afford it for less than \$35, instead of \$40, as stated in our former issue. We can fill orders on short notice just now, as we are still not badly crowded. Remember this machine saws and sandpapers the sections all at one movement, and does not require skilled help to run it.

OUR NEW MACHINE FOR MAKING THE FOUR-PIECE DOVETAILED SECTION.

This is by all means the cheapest rig a supply-dealer can use for making section boxes, for it does away with the necessity of an expensive cigar-box planer.

A HOME-MADE BUZZ-SAW FOR MAKING HIVES.

THE WAY FRIEND HESELTON MADE ONE, TO BE TURNED BY HIS TWO BOYS.

I HAVE been a bee-keeper for twenty-five years, but it has been only about ten years since I commenced with a frame hive. Since that I have taken a great deal more interest in the bee business, yet I have not made much of a success of it, as I have had a farm to attend to, and that has taken most of my time; but I shall never give it up while I live, for I love the "little busy bee."

After I commenced reading GLEANINGS I found there was a better way to make hives and frames than with a hand-saw; but to buy a Barnes foot-power would cost me more money than I could spare; so I set about building one. In the first place, I went to the blacksmith shop and procured a piece of inch round iron, 20 inches long. I filed the ends square, and obtained the centers. I then filed down the journals, and the end where the thread was to be cut, and I did all the filing with one Nicholson ten-inch file. I then put a small pulley on the shaft, and hung it on its centers, in a little frame made by nailing some two-inch strips across some other strips of the same kind. I filed some screws to a point, for the centers to run on, and clamped the frame to an old sewing-machine table. I then took two eight-inch flat files that had been worn out, and ground them into right and left chisels, to turn my journals true, which I accomplished at odd spells. I then took the shaft to the shop, had a collar shrunk on for the saw to rest against, a thread cut, and a nut put on to hold the saw. He also made a loose collar for the nut to work against. For the iron and work he charged me one dollar. I then took it home and put it into my lathe, and did what turning was then needed. Where the saw went on I had to turn down to $\frac{3}{4}$ of an inch, as it would not make a plump inch, when it was made round.

I then built a table, about 4 feet long and 3 feet wide on top. The top is a frame, and hangs on hinges at the back end, so that it can be raised and lowered at pleasure. The right half of the table runs on slides like the Barnes, but the slides are inch ash. I raise the table by placing blocks under it, of the required thickness. I then built a driving-wheel 4 feet in diameter, by nailing three thicknesses of inch lumber together, cut out like fellows to a wagon-wheel. The spokes are also inch lumber, and six in number. The hub is made of some heavy tough lumber, cut into wheels about a foot in diameter, and securely nailed to the spokes, and two of these wheels on each side. I then planed up a tough hickory shaft two inches square, turned down the journals to about $1\frac{1}{2}$ inches, put a crank on each end, hung the wheel so that it would run true, and put on my belt, which a saw-mill man gave me. It was an old piece of 4 ply belt. I cut off a strip 3 inches wide, and pulled it in two, and it works all right. The saws are 8 inches in diameter, which you ordered for me from Fitchburg, Mass. The shaft runs in wooden boxes, babbitted, and now with one of my boys at each crank I can cut up inch lumber rapidly and nicely. In $\frac{1}{2}$ -inch lumber it sings like a top.

I want to build me a wooden turning-lathe. If there are any of the readers of GLEANINGS that

have had any experience in that line of work, I should be glad to hear from them through that medium.

G. H. HESELTON.

Valley, Lewis Co., Ky., Feb. 9, 1885.

Such a machine as you describe, friend H., will do a large amount of work, without doubt; but it strikes me you ought to have a pretty good family of boys, if you expect to drive much of a business. While two are turning, there ought to be about two more having a good rest, so as to take their place presently. As your business increases, very likely the boys will begin to plead for a little steam-engine; and if they will put in and help their pa, there will not be any trouble in paying for it. Your large wheel should, by good rights, be entirely below your buzz-saw table, so your belt will not ever be in the way in cutting off long boards. You can either put the boys down a little lower than the floor, or else elevate yourself and the saw-table a little higher than the floor. Thanks for your description of the way you did the work yourself, so as to save expense.

MY REPORT.

CAN HONEY EVER SUCCESSFULLY COMPETE WITH SUGAR, AS A HOUSEHOLD SWEET?

I COMMENCED the season with 10 colonies of my own, all in good condition, and 8 colonies on shares which were in fair condition. The early part of the season promised exceedingly well, and my bees never gathered as much from apple-bloom before. They filled up the spare room in the brood-chamber, besides storing a considerable surplus, and becoming strong in working force, and in unusually good trim for a successful summer's business.

However, white clover did not yield much honey; and basswood, of which we have but little at best, yielded next to nothing. Buckwheat did well for as dry a season as we had, so did Spanish needles; but the yield from those sources is not large in this section. Taken all together, the past season was considerably below an average one. I produced all comb honey. My own colonies averaged me 36 1-5 lbs., spring count, with 80 per cent increase, and those I ran on shares averaged 29 $\frac{1}{2}$ lbs. and 100 per cent increase. I sold all my honey near home, at from 16 to 25 cents per pound, the first being wholesale and the latter retail prices.

I found the market at times almost glutted with honey, and it was dull work to make sales at such times. I have produced honey for more than 20 years, and have sold at prices ranging from 15 up to 40 cents a pound for comb honey, and am at present strongly of the opinion there can be an overproduction of honey, and that we are not far from it now. While many think that honey should be as commonly used, as a sweet, as sugar now is, it must be recollected that it is generally considered more of a luxury than any thing else at present, and I doubt if we can ever produce it cheap enough to get it out of that position, and live.

EMBARKING ONE'S ALL IN THE HONEY BUSINESS.

I have always been too much of a doubting Thomas to make the bee business a specialty, and "risk all in one ship," and am therefore engaged in fruit culture in connection with bee culture, and find it pleasant and agreeable as well as profitable.

I now have 9 acres in orchards, 3 acres in raspberries, and $\frac{1}{2}$ acre in strawberries, and intend to plant between 3 and 4 acres more to raspberries and strawberries next spring. At some future time I will try to give you some further reports as to my success in the undertaking. SAMUEL RAY.

Columbiana, Ohio, Feb. 13, 1885.

Friend R., I am afraid you are doubting a little too much, are you not? It is my impression that there are many who prefer to raise honey instead of doing something else, even if the price should come down so as to average not more than the price of white sugar, as it is now retailed in our markets. Of course, there are many who have other work that would pay them better; but those who love the bees and the business, I think would still save the honey when it comes, and I am not sure but it will eventually prove to be the cheapest sweet, all things considered, that can be obtained.

HEDDON'S HONEY-RACK COMPARED WITH J. P. MOORE'S.

ALSO SOMETHING IN REGARD TO MORAL PATENTS.

FRIEND ROOT:—The honey-rack described on page 85 of GLEANINGS is not like Heddon's. 1st, because it does not make any arrangements for bee-spaces at top and bottom of the sections; 2d, It is an inside case; i. e., it needs another outside of it, for we infer the case is to hold only the bottom of the sections, for no sensible bee-keeper would think of using sections 6 $\frac{1}{2}$ in. long and only 2 $\frac{3}{4}$ in. high. The Heddon case covers the sides of sections entirely; 3d, There is no arrangement for tiering up in the Moore case. I have used a case essentially the same, and do not like it. But the Heddon case I have yet to find any fault with, and any claimed improvement on it has been, as Mr. Heddon says, only adding a defect. As I do not remember to have seen any thing in print giving its points of merit, I herewith inclose an article on that subject.

I will say, in regard to the "moral-patent" business, I wrote Mr. Heddon, as friend Hutchinson suggested, and received a very neat and gentlemanly reply from Mr. Heddon, which was quite satisfactory, as far as I am concerned; and yet I am not satisfied that "moral patents" are just right, or that bee-men are more apt to respect the rights of others than any other class of men. The paying for a right to manufacture should also include the defense of that right. Suppose that now, after you have paid Mr. H. \$100 for your right, some other large establishment, with a less conscientious man at the head, advertises and makes them for almost half what you do, do you think that he would not get the custom? Would bee-men be willing to pay more for a thing of your make than for another made equally well? Would the blame rest on the bee-man if he did buy of him, the cheap manufacturer? Would he be justified in taking the money from his family, to pay you the extra price? Now, this is a supposed case; but it is also true in fact, as the inclosed leaf from a well-known manufacturer's catalogue will show.

Allow me to criticize Heddon's article in one point. It might be inferred from the paragraph on the honey-board, that bees would not build comb

between it and the tops of the frames, which is wrong, for they will do so. I have never used one myself, but a neighbor has, so I know from personal observation. Also the engraving of his hive is wrong in one particular. It would appear from it that the slat honey-board had strips running cross-wise with the frames, which is not a fact.

WIDE FRAMES VS. HEDDON'S CASE.

1. It dispenses with separators, saving expense, and making one less "trap" to have around.

2. It keeps sections free from propolis, by having proper bee-spaces above and below the sections, and covering the sides entirely; at least, this has been my experience, and I infer that others have had the same, from the "boom" they got at the Michigan convention.

3. The sections are brought down closer to the brood-frames when putting on the first sections at the commencement of the honey-flow; i. e., to get the bees at work in sections you do not have to put them so high up, and away from the heat of the brood-nest, which is important in preserving the heat of the hive. It is true, one might, by putting wide frames at the side, or by division-boards, obviate this objection to wide frames, but this makes more "putter" and more "traps" around. I find that, in practice, one case of 28 sections is seldom too much for a colony to start on.

4. It admits of tiering up, without putting on more room than the bees can heat up to the proper temperature for wax-working. The sections which are nearest finished, and which ought to be ripened fastest, are always kept at the top, where the greatest heat is supposed to be.

5. Cheapness. A hive complete with two wide frames is put at \$3.50, which is to hold 48 sections; one hive, complete with two cases, or 56 sections, at \$3.00—a difference of 50 cts. in favor of cases, and room for 16 sections more. This would make, I presume, a difference of \$60.00 on furnishing an outfit for 100 colonies—quite an item!

6. Ease of handling. In filling wide frames I have had trouble in handling the frames when full of empty sections; they would slip out on the side where there was no separator, or would get moved a little, just enough to bother, or the bottom-bar would get sagged, and leave a space in the middle at the top, and thus throw the sections out of square by their own weight, when they were being filled. A section can not get out of place in a Heddon case; it can't drop out, nor get in the way of another. Sections are easier put in and easier taken out of a case. There is no prying up of frames, no gluing together of frames. The sections will usually drop out themselves when the case is turned bottom up, and can thus be emptied while you would be getting wide frames out of a hive. They are easier to handle when full than a hive full of wide frames, for your load is in two parts; this is quite an item when, for any reason, you wish to get at the brood-combs.

7. They may be reversed, which is quite important in getting sections sealed over quickly.

There are some minor points I might mention, but think these are enough to convince the most skeptical; but if there yet be any doubting Thomases, I say, let them send to Mr. Heddon and get enough to try, and be convinced. But before closing I would remind any one who thinks of dispensing with separators that three things are all important. 1. Sections must not be over 1 $\frac{1}{4}$ in. wide, but

may be narrower; 2. Full-sized starters of foundation are necessary; 3. The hive must stand so the sections will stand plumb sidewise; *i. e.*, not lean so the foundation will not hang just in the center of the section.

C. A. HATCH.

Ithaca, Wis.

I know of the difficulties, friend H., in the way of the moral-patent business, and I do not wish to be understood that I mean to advocate moral patents in place of our patent-laws. It is too large a subject for me to even attempt to handle. I can do this, however, and like to do it: Whenever I want to use some important idea advanced by somebody else, I like the idea of paying him for it, or for his consent to my using and advertising it, if you choose. I hope the brother who sends out the catalogue of which you inclose a leaf will change his next issue, or else make some arrangement with friend Heddon to let it remain as it is; that is, if he continues to advertise "*Heddon's Hive*" he should first purchase the right to use Heddon's name as an advertisement for that class of hives.

ALSIKE CLOVER AS A FORAGE AND HONEY-PLANT.

A PAPER READ AT THE CONVENTION AT VASSAR, MICHIGAN.

HAVING made some experiments with this clover that proved very satisfactory to myself, I thought to give the result of those experiments to this convention, hoping that it will be of some interest to bee-keepers, and to farmers in general. I will first give a description of the plant and its growth.

ALSIKE, OR SWEDISH CLOVER—*TRIFOLIUM HYBRIDUM*.

So called from being intermediate in its appearance between the red and white clover, possessing qualities common to both. It makes but little growth the first year, seldom blossoming in our latitude. But the second year it comes on as fast as red clover, sending up from 3 to 5 seed-stalks in a stool, which throw out numerous side branches, making a succession of bloom for about four weeks. The root is unlike our common red clover, from the fact that it has but a small center, or tap root, and throws out numerous side-roots, which makes it well adapted to low land, or any land that is liable to heave. The stalk is little if any larger than our common timothy grass, growing from one to two feet in height, being well covered with fine leaves, having blossoms similar to our common white clover, but about one-third larger, bright pink in color, fading to white. The seed is about the size of a timothy seed, with the hull off, growing with from 3 to 5 seeds in a pod, the same as white clover. One peculiarity of this clover is, that it makes but little second growth if the seed-stalk is allowed to form; consequently the first crop has to be saved for seed, being similar in this respect to mammoth or peavine clover.

I consider it fully as good for hay as timothy, being fully as free from dust when cured. Having been well satisfied of its value for a hay crop for some ten years, I decided, in the spring of 1883, to seed three acres of land with clear alsike, and make an experiment as to its value for pasture, honey,

and seed. The piece I decided to seed was 12 by 43 rods, crossing what was once a black-ash and elm swail, now well underdrained. About two-thirds of the ground was low; soil a black sandy loam, the high ground hard clay, the whole ground being in fall wheat when I sowed the seed in April, 1883. I sowed 4 lbs. to the acre, and in October following I top dressed the high ground with well-rotted manure, putting on 14 two-horse wagon-loads. In April, 1884, the clover came on very rapidly, so that by May 1st I turned 5 cows and 3 hogs into the field. May 24 I put 2 horses in the field, and the last five days prior to shutting all stock out of the field, which I did June 15th, I allowed 40 sheep on the ground. As a forage plant I will speak hereafter.

PASTURING ALSIKE SO AS TO MAKE IT BLOSSOM IN AUGUST.

Knowing its peculiarity of not growing a second crop if the seed-stalk was allowed to form, I pastured it close. I know it has been stated, that if it was cut in June, just as it was coming into blossom, that it would blossom again in August. This is a mistake. In our latitude the seed-stalk must not be allowed to form. My object was to have it come in blossom about July 20. In this I failed. It commenced to blossom July 8th, when it was about 4 inches high; and by the 15th, 40 rods away, it looked like a field of snow, and the aroma of the blossoms could be smelled very plainly that distance. The bees commenced to work on it with the first blossoms, and continued to work until Aug. 1, for two weeks of the time with a perfect roar.

My failure to have it come in blossom at the close of basswood bloom, as the season turned out was just what I wanted, for basswood failed to furnish any honey; and had it not been for this I should have had no white honey to speak of. The last of August the seed crop was ready to cut, having attained a height of about one foot. I secured the crop by cutting and curing, the same as though it were hay. I thrashed it in November, and got 540 $\frac{1}{2}$ lbs. of seed, cleaned ready for market.

AS A FORAGE-PLANT.

It has no superior, producing a large flow of very rich milk. June 15th, when I shut the stock out of the alsike, I allowed them to run in a field of red clover that was just coming into blossom, and at the end of the third day the five cows had shrunk their milk to the amount of 9 quarts to the milking. Again, in October, to test it further for feed, as there was quite a growth of leaves on the ground I again allowed the cows in the field. You may judge of my surprise when I found, at the end of a week, they had made a gain of 10 quarts to the milking.

I had, July 1st, 20 swarms of bees that I was working for comb honey, and from the alsike blossom I obtained 20 lbs. per colony of very nice white honey in one and two pound sections. As a result I have sold quite an amount of seed to my neighbors, and I shall sow five acres to clear alsike, and about one pound to the acre on ten acres, with other seed, this coming spring.

I would recommend all bee-keepers to get it introduced in their vicinity as a paying crop for the farmer, and a never-failing source of honey for themselves.

The seed is the cheapest now I ever have known it to be. A. I. Root, of Medina, Ohio, is selling it for 20 cts. a pound, or \$10.00 a bushel, so that, by sowing four pounds to the acre, which is a great plenty, the cost will be but 80 cts.

This coming season I shall pasture the piece I have in about 12 days later, so that, if it matures the same as it did this year, it will come into blossom about July 25.

M. D. YORK.

Millington, Mich.

HOW TO MAKE A CHEAP HEN'S-NEST.

AFTER my remarks in the former number, in regard to a hen's-nest, I happened to find, in an old *American Agriculturist*, something like the cut below. A common flour or sugar barrel is all that is needed.

You can buy one at the grocery for about ten cents, usually. Saw a hole in it like the illustration, only our artist has got it upside down. The V-shaped cut should be uppermost, then when biddy starts to step out she won't be interrupted in the midst of her cackle by slipping up. Nail securely to the hoops the staves that are cut, then the barrel will not be coming to pieces, even if we have dry weather. The material for the nest may be ground moss, straw, or any thing you choose; and if, in the course of time, the institution should become a harbor for vermin, it won't cost very much to saturate every part of it with kerosene. The opening can be easily turned toward the wall, so that the inmate can enjoy the proper amount of retirement from the busy, gossiping flock, while she deposits her snow-white or buff-brown egg, as the case may be.

TEN-CENT HEN'S NEST.

SWEET, OR BOKHARA CLOVER.

SOMETHING ABOUT SOWING IT ON BLEAK HILLSIDES, WHERE NOTHING ELSE WILL GROW.

AS it is about the time of year when bee-keepers begin to ask the question, "Shall we sow any thing to keep our bees busy and out of mischief after the natural pasture is gone?"

I should like to give a little of my experience with sweet clover. It has generally been classed among the weeds, and not as a forage plant; but this is not strictly true, as stock of any kind will feed on it very readily in the *early spring*, or during any dry season when better pasture is scarce; and besides that it is a great fertilizer, as the roots will penetrate 4 or 5 feet into the hardest clay soil, and will leave the soil very mellow, and in good condition for another crop. It is a perennial, bearing seed the second year when the roots all die.

If you wish to seed a piece permanently, it is better to sow seed two years in succession. On our river place we had a barren hillside, too steep to plow, that had always been utterly destitute of any kind of vegetation. I had tried in vain to seed it to white and red clover, and other kinds of grass. Five years ago I sowed it to sweet clover, and ever since it has produced a splendid crop of honey every year, from July till frost killed it. The sweet clover has so mellowed the ground that it is now well seeded to white clover, which will, in a year or two more, entirely swamp out the sweet clover.

Any bee-keeper who has too poor a piece of ground to raise any paying crop will find that a crop of sweet clover will pay well in honey, besides having a crop second to nothing to plow under in the fall for wheat or rye. You need not fear it as a weed, as its profit greatly outweighs any little trouble you may have in that direction. I regard weeds as the poor farmer's best friend, as they compel him to cultivate his crops, and will fertilize his land when he lets it lie idle.

If you wish to plow it under, sow it pretty thickly (as the stalks and roots will not be so large). Sow from a peck to $\frac{1}{2}$ bushel per acre; 4 or 5 lbs. will seed an acre for a honey crop.

Medina, O., Feb. 14, 1885.

H. B. HARRINGTON.

In connection with the above I would remark, that we have a fine stock of seed that we can furnish for 20 cts. per lb.; 10 lbs., \$1.80, or 100 lbs. for \$15.00. By mail, 18 cts. extra per lb. for bag and postage. If you have any piece of ground so hard and barren that nothing else will grow, try the plan given by Neighbor H. I have for almost twenty years noticed the hillside he speaks of, and wondered why there was not something that could be made to grow on it. There is no more need of its being a troublesome weed than common red clover, if we plow it under, on the plan suggested, when you want to get rid of it.

J. F. FLORY'S SECTION-CLAMP.

As Described on Page 100.

FRIEND FLORY TELLS US ABOUT IT HIMSELF THIS TIME.

I WANT to call your attention to one thing, and that is, those corner clamps that Mr. Geo. Hobler, our secretary, sent you a few days ago. I have been using the wide frames with sections, more or less for nearly ten years; but the greatest objection I ever had to them was it took too much time to handle the honey, especially here in California, where honey is cheap and labor high. I finally offered \$5.00 for some kind of clamp, or contrivance, that we could clamp them all together with, and handle them like a solid box, like what we here call the "Tulare sectional case," in which shape nearly all our comb honey is put up, and is cheaper and better than the Harbison section.

I thought of those corner clamps, perhaps a hundred times; but there always seemed to be some objection to them, for some cause that I can not now explain. But I finally rigged up the Barnes sawtable and sawed out a few, and put them on one of our sectional cases, when I saw in an instant that I had it, and exclaimed, "There, now, I've got it, sure," and started for the house to show it to my better half, who was also delighted with it. You see, friend Root, we are partners in bees and every thing else, as well as the babies, which are only 6, the eldest 12 years old, and the youngest 11. So I fixed up a lot of sectional cases, intending to take them to our quarterly bee convention at Hanford, in Dec., 1884, but being quite unwell I did not get to go; but at a special meeting in Fresno, Jan. 7, I presented them, and every one was enthusiastic in their praise, and there is not a comb-honey producer that belongs to the Central California Bee-keepers' Association that saw it, and some that don't, but say they intend to use them. Their use will ne-

cessitate a honey-board; but, unlike the Heddon case, only one. By sawing them $\frac{1}{8}$ of an inch plump, we have the proper space, between each section case, which facilitates their handling, without killing bees, and it seems to me much better than two spaces and a honey-board besides, like Mr. Heddon's.

There is one thing the bee-men here are satisfied with, and that is, it is going to revolutionize the manner of putting up comb honey here. With the low price of honey and high price of labor, we must have our honey in shape so as to handle it rapidly, and, at the same time, in a neat and attractive form; if it is not, as you have several times mentioned, "gilt-edged honey," it certainly is "border-edged," as those clamps form a neat and attractive border.

Please tell everybody on this coast that our annual bee-keepers' convention will be the first Wednesday in March, at Hanford, and every three months thereafter, *always* the first Wednesday in the month.

J. F. FLORY.

Lemore, Tulare Co., Cal.

Thanks, friend F., for your kind letter, describing your invention. Evidently, you had not yet received your GLEANINGS for February when the above was written, for you do not answer in regard to the manner of closing the ends of your boxes. You also, in tying up, have a double bee-space, if I don't make any mistake.

ARTIFICIAL INCREASE.

HOW AND WHEN TO UNDERTAKE ARTIFICIAL SWARMING.

G. M. DOOLITTLE, *Dear Sir:*—Would it be possible for you to give us an article in GLEANINGS on artificial increase, after the nucleus system?

A. H. NASH.

Santa Monica, Cal.

A few days ago I received the above; and as I have other like requests I will comply, by here giving the three plans of artificial increase which I prefer, after trying nearly all the plans I ever read of. I first wish to say, however, that for this locality I prefer natural swarming to any plan of artificial increase, where only one swarm is allowed from each old colony, and where said swarm will issue in time to prepare both old and new colonies, in good shape for the honey harvest.

The first plan I will give of artificial increase is what is termed by some the "nucleus plan." To be of the most value, the nucleus should be formed 20 to 25 days before the honey harvest, by having enough bees in it to protect a frame two-thirds full of brood, the larger part of which should hatch during the first four or five days, while said comb should contain some eggs just laid, if possible. Besides this frame of brood and bees, the nucleus should contain a frame having a pound or two of honey in it, the whole being set in a hive, and confined to one side by means of a division-board. The next day after making, a mature queen-cell should be given, or a newly hatched queen introduced. In about ten days, if all proves favorable, the young queen will be laying, when I go to the hive from which I formed the nucleus, and select a frame of brood, nearly all of which are about gnawing out of the cells, and add this to the nucleus, always putting a frame of comb or foundation in the old colony

to take the place of the one taken out. I now wait four or five days, when I go to the old colony and take out 5 frames of brood, from which all the bees are shaken (as they were from the last-mentioned comb), when I carry them to the nucleus. I now fill out each hive (I use 9-frames in a hive), with empty comb or fdn. and put on the surplus arrangement. By the above, each colony is made of about equal strength, and the brood is so taken out of the old hive that the colony does not have a desire to swarm. This old colony will have the most field-bees for the first week or so, but the other will soon make the stronger colony of the two.

My next plan is to make one colony from each old one, on the principle of division of the bees, instead of the brood, as in the above case. In using this plan we wish queen-cells nearly mature by the time our first colonies are preparing to swarm. Having such cells on hand I go to a colony preparing to swarm, or one that has its hive full of bees and brood (if the hive is not thus full it is useless to try to increase them), and move it a few feet to one side of its old location, so as to put a new hive in its place. I now look over the combs until I find the one having the queen on it, when I place said comb in the new hive. Next I give them a frame having some honey in it, and then fill out the hive with empty comb or fdn., when about two-thirds of the bees in the old hive are shaken in front of the new hive, and allowed to run in. After this I arrange the frames back in the old hive, putting in a division-board in place of the frame taken out, when the old hive is carried to a new location, where I wish it to remain. After the bees thus removed have become reconciled to their queenless condition I give them one of the nearly mature cells, or a virgin queen which will soon be laying. In this way I have secured my new swarm, controlled all after swarming, and introduced my young queen all to my liking, and with but very little trouble.

The third plan is one I use on colonies which do not swarm up to ten days before the honey harvest, when I proceed to make colonies from them as follows: A hive is filled with frames of empty combs, and placed upon the stand of one of these colonies which has not swarmed, and all the boxes are taken off and placed thereon, then all the bees are shaken and brushed off their combs of brood and honey, in front of this prepared hive, into which they will run as fast as shaken off. Thus I have a colony that is ready for the honey harvest, as they have the queen, bees, and partly filled boxes all in readiness for work. Previous to this, nuclei have been started, so I have plenty of laying queens to use as I need them. I next take all the combs of brood from which the bees were brushed, except one, arranging them in the hive the bees were shaken out of, and carry them to the stand of another colony which has not swarmed. Next I take the comb of brood which was left out, and go to one of the nuclei, taking out the frame having the laying queen on it, and place the comb of brood in its place. Take the frame, bees, queen, and all, and set it in the place left vacant for it when arranging the combs of brood. Now put on the boxes, and, having all complete, I move the colony to a new stand, and set the prepared hive in its place. Thus I have a laying queen, and enough of her own bees to protect her, together with a hive filled with combs of brood, and all the field-bees from the removed colony. The loss of bees to the removed colony stops

the swarming impulse, and in about a week they have so regained their loss that they are ready for the boxes again. In this way I make only one colony from two old ones, but have all in the best possible condition to take advantage of the honey harvest.

G. M. DOOLITTLE.

Borodino, N. Y., Feb. 13, 1885.

WIDE VS. NARROW TOP-BARS.

FRIEND ALLEY'S IDEAS IN REGARD TO THE MATTER.

OF late there has been a good deal said in the journals about the bees building comb between the top-bars, honey-board, or the caps. If the hive is properly constructed, there need be no complaint on this account. I have read something about "nuisances in the apiary;" but in all my experience in bee-keeping, the biggest and worst nuisance is the *narrow* top-bar to the movable-frame hive. Mr. Langstroth saw this defect in the first frames he devised, and soon discarded the narrow bar for a wide one, and at the same time gave his space between the top-bar and the honey-board above.

Now, is it really necessary to have a "sink" honey-board where the hives and frames are made as above? I have never used a narrow top-bar in my apiary, but had occasion to work on hives for other people, where the top-bar was but $\frac{3}{8}$ of an inch wide. The first move would be to pry off the honey-board, and with it several pounds of honey and wax. Before proceeding further, the bees must have time to clean up the loose honey; and then what a fine job it is to get out such frames! It is almost vexing enough to "make a minister swear."

Last year I bought 20 three-frame nucleus hives, all having *narrow* top-bars. If the bees and I live until spring, there will not be one of them on my premises after May 10. What possible objection can there be to a $1\frac{1}{2}$ -inch-wide top-bar? The apiarist who has never used them knows but little about how nicely they work, and with what ease and comfort he can open and examine a colony of bees, compared with the hive having narrow bars. Beekeepers about here have used the former for over twenty years, also *thin* honey-boards, *slatted* honey-boards, and, in fact, all kinds, except those made of perforated zinc; the result, so far as a crop of honey was concerned, was all the same.

The frames having wide top-bars should be spaced so that there will be not quite $\frac{1}{8}$ inch between them at the top, and there should be the same room between the top of the frame and the honey-board, or whatever is used over the frames, and no comb of any account will be put in between. The L. frames with a top-bar $1\frac{1}{2}$ inches wide will just about fill the space of the L. hives; that is, where the hive is $14\frac{1}{2}$ inches wide. The dimensions for a standard Langstroth hive, as Mr. L. has given in his book, are $14\frac{1}{2}$ inches wide, $18\frac{1}{2}$ inches long, and 10 inches deep.

All the frames in the twenty nuclei I received last year were made for hives that should be $\frac{1}{2}$ inch longer than the above. All these frames had *tin* corners to keep them from getting out of square, but every one of them was $\frac{1}{2}$ of an inch lengthwise out of square, and for that reason I shall cut the combs out of every frame, and put them in others that have no tin corners. I never have anything to keep my frames square, except the nails, and none of them are out of true.

I have received several frames lately (samples of the reversible arrangement), and all had the narrow top-bars. To me, this is an objectionable feature; but I did not see how a wide one could be used where the reversing arrangement was affixed to them. Well, I set my wits at work, and soon devised one that the wide top could be used on. A sample will be sent you soon, also cuts, to show them in GLEANINGS. You will see that this arrangement is very simple, practical, and easily applied. The top-bar is held firmly in place, and the frames are as firm as need be. All the work, but nailing, can be done with the circular saw.

Wenham, Mass., Feb. 6, 1885.

H. ALLEY.

Friend A., I know there are some who prefer top-bars more than one inch wide; but before getting out our metal corners I experimented pretty thoroughly, and used hives with top-bars of different widths for several years. Those having a top-bar $1\frac{1}{2}$ inches wide troubled us more in the apiary than any thing we ever used. The bees were continually bridging from one to the other, so as to make the whole top look like a solid chunk of combs and sticks. Somebody (and I am inclined to think it was J. H. Townley, the father of the chaff-packing arrangement) suggested frames $1\frac{1}{2}$ inches wide, with the top-bars beveled off so as to present only a sharp knife edge along the top edges. I think likely these would work better; but the way we handle combs for queen-rearing, it seems to me no width is so convenient as the orthodox $\frac{3}{4}$ -inch. I should be glad to have the experience of many of the friends in this matter.

HOW TO TELL WHEN SECTIONS ARE FILLED, ETC.

IS IT ONLY THE VERY YOUNG BEES THAT SECRETE WAX?

ISEE by Feb. 1 number, Mr. Robbins has been writing for my benefit; and as I have had over twenty letters from other friends, telling me how to find out when the Heddon case is full and capped over, it is about time I should know how to use them to advantage; but, friends, I am as bad off as ever; and although I am thankful for the advice, none have yet told me how to tell when they are full, without disturbing the bees, which you must do when you take off the cover; and before it can be put down, the smoker has often to be used to drive the bees down. With the case I use you have only to lift off the top story, and look through the glass. I use the wide frames the same way, by putting two strips of glass on each side, and cut off the arms so you can set a Simplicity top over them. They can be held together by a small wire or string.

I believe I said once before, that after a bee got old enough to be a worker he could make no more wax. The editor seems to differ. Now, to prove that a worker could secrete no wax, which I claim is a product of the bee which it yields before it is old enough to be a worker, I built me a hive with a wire division-board separating two frames from the others. I put all the workers on one side, and the young bees and queens on the other, with the entrances to each apartment at opposite ends of the hive. To keep this colony of workers strong, I got

1 lb. of blacks from a breeder, 7 miles off, once a week, to make them store honey fast. I fed at entrance, and soon found that they were passing the honey through the screen, and the young bees gave them scales of wax to build comb. I spoiled that by putting in a double screen. They then filled their hive full of honey, but could not cap it. I one day laid out some sections with foundation, and soon found that the bees were cutting it up and carrying it off. It proved to be my blacks, and they were capping over their honey, and I never saw bees work harder; at no time could I find a wax scale on any of these bees. W. CONNELLY.

Ogden, Iowa, Feb. 9, 1885.

Friend C., it is true that in the Heddon case the strips of glass are omitted, that we have been in the habit of putting in our crates for years back; and as the sides of the crate go right out to the weather, it would be hardly advisable to put in glass as in ours. With the crate to go in the inside of a Simplicity hive, however, there is no reason why glass should not be put in if it is wanted.—Your question about the age at which bees secrete wax scales depends a good deal upon what you call a young bee or an old bee. I have always been of the opinion that bees of almost any age could secrete wax for comb-building, if they were obliged to; but Langstroth tells us in his book that young bees—at least the principal part—do the comb-building. Your experiment is quite an interesting one. A worker-bee goes out to the fields when about two or three weeks old, if I am correct; and if it is true, that he never hangs in clusters, nor secretes scales of wax after this age, it is something new to me.

A CHAPTER FROM THE EXPERIENCE OF AN A B C SCHOLAR.

HOW I GOT MY FIRST COLONY.

I WAS in the woods, and by chance found it clustered on a chunk of wood that had been split out of a tree to get the honey, and the party, as usual in this section, left the bees to take care of themselves. When I first saw them my first impulse was to run away; but seeing they were not so much for flight as I thought, I ventured a little closer, and found them nice yellow fellows, but I had no thought of living them; but when my wife heard my story she insisted soon having them that I could not refuse her. The next thing was, "What shall we put them in?" We had no hive, so I took a box about one foot square, bored holes for cross-sticks, and started for my bees; and by the time I got there my heart was beating more than you know, and I was so nerveless that my whole body shook. This is what I call some of my experience. Well, I brought them home without any trouble, and put them on a stand. This was about the last of July, 1883, and the swarm was a small one, so we fed them sugar syrup, and some of my neighbors told me I would kill them, so I quit feeding for about one month; then came the A B C book. I opened it, and about the first thing my eyes met was "Feeding and Feeders," so I went to work according to your directions, and fed them for winter. They were in a box made of 1½-inch boards, and so I put the bees (box and all) into an-

other box, and packed straw between the two; they came through all right. During the winter I bought four more. Now for my report. I commenced in spring of 1884 with five colonies.

First, cost.....	\$ 3.60
Second.....	5.00
Third and fourth, \$3.10 each.....	6.20
One S. hive.....	4.00
100 wide frames and other fixtures.....	42.05

Total.....	\$60.85
------------	---------

I sold one colony.....	\$7.00
Comb honey, 12 lbs. at 25 cts. per lb.....	3.00

Total receipts.....	\$10.00
The bees owe me.....	\$50.85

How is that for "high"? Oh! hold on! I have eleven colonies here yet. They are worth \$7.00 each. I would not say that, but I could sell them for that money.

THE WAY IN WHICH FRIEND K. AND HIS WIFE MADE PROGRESS DURING THEIR FIRST SEASON.

There is but one man in my immediate neighborhood who has the movable-frame hive, and he has the S. hive; my wife and I did our own transferring, and some other that I did not give in my report. We did it all in time of apple-bloom. It seems to me your bees are harder than the bees here, or at least they do not dwindle as the rest of my bees do. The colony that I gave the queen to, which I got of you, stands the winter better than the rest do, and they had no better treatment than the rest of my bees. They are all in Simplicity hives, with division-boards filled back of them with chaff and old clothes. The colony above mentioned does not fly as much as the rest when it comes off warm, yet they are as strong as any of the rest.

I have some spider-plant seeds of the *Cleome speciosissima*, and it yields lots of nectar. If you want any of this I can let you have about an ounce, at whatever you think right. It grows about 5 ft. high, and branches a good deal. The branches grow about 3 ft. long. I gathered that seed all from five stalks; but, oh what great drops of nectar! and the bees found out that it was sweet, and they carried it all away.

Now, friend Root, for the tobacco, last but not least. I am now 32, and have used tobacco since I was about 14, both chewing and smoking. Sometimes I would quit for a little while, and then at it again, but I was ashamed to smoke where people would see me, and still I clung to it, and it bound me in its chains so completely that now it is no easy task to break its fetters; but, brother (if the word "brother" seems out of place excuse me, but it seems the right one to me the way I use it, that in Christ), I am a teacher in Sabbath-school, and one of my scholars said to me one day, "Why, you have been smoking; I can smell it in your breath." Do you know how that has bothered me since? Just think of a man trying to lead others, when he is blind himself. God does not want the blind to lead the blind, but he wants those who can see to do that work, lest they both stumble and fall, so I have made up my mind to try to quit the use of that filthy weed, and I now take my stand with many others. Will you pray for me? God help me, is my simple prayer. It is no easy task. The spirit is willing, but the flesh is weak. J. A. KIME.

Fairfield, Adams Co., Pa., Feb. 2, 1885.

Many thanks to you for your kind letter, my good friend. So the credit of your bee-keeping belongs much to the energy

and zeal of your good wife; and it does me good to learn of instances showing how much we are indebted to our wives.—I shall be very much obliged indeed, friend K., for some seeds of the *Cleoma speciosissima*; and I am rejoiced more than you can tell, to know that you are determined to listen to the voice of God which came to you through one of your pupils in your Sunday-school. Do not, I beg of you, turn back on this message, but hold on and press forward, Christ helping you. You can not tell how heartily I thank God for having given me the means of helping to lead souls to purity and godliness, as well as to teach about the honey-bees.

FRIEND KLIMITZ'S QUEEN-CATCHER.

AN INVENTION FOR PEOPLE WHO FEEL NERVOUS WHEN THEY ARE OBLIGED TO HANDLE QUEENS.

WITH today's mail I send you a sample of what I call my queen-catcher. You may smile at the simple thing, or perhaps throw it aside with contempt; but I assure you it has been for twenty years, and is yet a perfect boon to me.

A MACHINE FOR CATCHING QUEENS WITHOUT INJURY.

Years ago, when I would not think of opening a hive of bees without having my hands protected by thick mittens, it was out of the question for me to pick up a queen with such clumsy fingers, and I had to get up something to help me out of the difficulty. This catcher was the result. All I have to do is to take out the plug from the open end, which has to be made in the shape of a funnel, and set this end lightly over her. As the light strikes her from above through the wire she will instantly run up into the cage, which is then closed by replacing the plug. Catching a queen in this way is just as quick as picking her up with the fingers, and, above all, she is never hurt. For a number of years I have not used gloves when at work with my bees, but I rely mostly on my catcher when I want to catch a queen, because I am a very nervous person, and can not keep my fingers quiet enough when I am in the least excited. They will tremble in spite of all I can do; and the more valuable the queen is, or the more anxious I am to secure her, the more unsteady my fingers are. But with my catcher I am always safe, and would not feel content, especially in swarming-time, without having several of them in my pocket.

To make the queen come out quickly I remove the plug and fold my hand around the cage to exclude the light, when she will run out at once, and into any thing I want her to. The string is only for the purpose of hanging the thing up in my honey-room, for I like to have every thing handy. This catcher I use especially when I want to make some disposal of the queen right away, except introducing. For this purpose I bore the other end out too (not funnel shaped, and as large as the piece of wood will

allow), and shut it with a plug, which is made hollow for about $\frac{1}{2}$ inch, and the hole filled with candy.

Now, friend Root, if you think it worth while to assist the nervous class of bee-keepers by mentioning this queen-catcher, you may do so; if not, you may throw it away. I shall be satisfied in either case.

CHAS. KLIMITZ.

Batavia, Genesee Co., N. Y., Jan. 24, 1885.

Friend K., your idea is certainly very ingenious, and the cage as sent us is a marvel of fine workmanship. Your idea of getting the queen out of the cage is especially a neat trick. I have been annoyed more in getting queens out of the cage, perhaps, than in getting them out of the hives. Very likely, when the queen is first put in there, and is anxious to get out, she would shoot out at once by simply shutting out the light with the closed hand; but after she has been in the cage several days, say by taking a trip by mail, I am inclined to think she would not go out so readily. Your whole implement would make a beautiful queen-cage. I may explain to our readers, that instead of wire cloth a great number of straight wires are used, about the size of a fine knitting-needle. We can furnish such queen-catchers to those who may want them, for an even 10 cents; and if the demand should be larger, possibly less; but I think we shall make them of wire cloth instead of wire rods.

CARP CULTURE IN TEXAS.

A FISH RECEIVED FROM THE GOVERNMENT, DEC. 10, 1880, WEIGHS 24½ LBS., AND IS 39 INCHES LONG, IN SEPT., 1884.

ED. GLEANINGS:—I am not a subscriber to GLEANINGS, nor am I a bee culturist; but my friend Buckner, of this place, is both, and he handed me your journal to see what you and your friends have to say about the German carp. In your Jan. No., 1885, I notice a letter from W. S. Kaler, of Andersonville, Ind., in which he states that he has a carp five years old that is 25 inches long and weighs about 14 lbs. I want to tell Mr. Kaler that I can double discount him. On Dec. 10, 1880, I received from Prof. Baird, 20 carp, from 2½ to 3 inches in length. I cared for them well, and last September I took out one and weighed it. Result, 39 inches in length; weight, 24½ lbs. This was one of my oldest fish. In Jan., 1882, I added 260, about the same size of the former when received, to my pond. I now have in a pond covering one acre in area, 280 old fish, and younger ones without number. My pond when full has a depth of 12 feet, and after a drought of six months' duration last year I had 15 feet of pure clear water. I depend alone upon the rainfall for water.

Now, this is a big fish story, but there are numbers of good men in this city who have seen my fish and will testify to my statements. I have made fish culture a study for the past ten years, the last four of which have been especially devoted to the carp. Carp do not hibernate in this climate, no going into kittles for a long winter sleep. They begin spawning here at two years old; and if well cared for, spawn by the million. They spawn but once a year, and the spawning season lasts only from 4 to 10 days. They begin to spawn here from the 1st to

the 10th of May. Their manner of spawning is as follows:

Males and females get together in warm shallow water; each emits its ova on the surface of the water, and then by fluttering agitate the water, and thus mix the ova of male and female; immediately after coming in contact, the egg is formed, and is about the size of a No. 8 shot. It is glutinous, and adheres to anything it comes in contact with, such as weeds, grass, or trash near the edge of the water. They will not spawn in deep cold water, nor in a shady place; and if compelled to do so the spawn is lost. The eggs will ordinarily hatch in from 8 to 11 days; but if the temperature of the water be raised to 90 or 100° Fahr., they will hatch in from 48 to 56 hours.

You ask Mr. Kaler to tell you how many can be raised in a pond of stated dimensions. This is simply a question of food and oxygen. Hundreds can be raised in very small ponds, if well fed. Oxygen is usually supplied in sufficient quantity by the atmosphere and wind to support them densely.

It will make this letter too long to give detailed plans for making ponds, construction of levees, screens, etc.; but if you desire, I may attempt in another, as well as to give other and further hints on carp culture in Texas.

L. T. WHEELER.

Corsicana, Texas, Feb. 13, 1885.

Friend W., it has for some time been conjectured that enormous results can be obtained in warmer climates than ours by the German carp, and your report is exceedingly valuable and interesting, inasmuch as it verifies these predictions. Our little book on carp culture will be out in a few weeks; and after you have looked it over, we shall be very glad indeed to have you add what you can in regard to the matter that is not already embraced in the book.

GROWLERY.

I DO not know where our moral patents are going to take us. At present it seems to me to have had the effect of stirring up the ugly feelings of humanity, perhaps even worse than politics. When a man has worked hard at something for many days, and passed sleepless nights over it, as friend Heddon mentions, it seems to have become a sort of child of his; and if you want to get into trouble, just abuse somebody's child—say he isn't smart or bright, or something of that kind. Whenever I pay something for an invention, I am immediately flooded with a great number of devices for different purposes. Of late, reversing devices have been beyond anything heretofore known. Well, I have been pained, and made to feel sad, many times, by the way in which my opinions have been received. Somebody writes me he is sure he has got just *the* thing; *his* device is the very center of the whole system of devices; in fact, the center of any thing that can be invented, for all time to come. Like the baby of the household, it is the handsomest, smartest, cutest baby that ever was known, and other babies are smart and cute just in proportion to their resemblance to said baby. Some may be pretty nearly equal to it, but none can be ahead, in the eyes of the father

and mother, and the rest of the family. Now, when one of these devices is submitted to me, and I reply that, in my opinion, it is neither new, novel, nor useful, the chances are that the inventor writes back that my statements are false in every particular—that I want it myself, or it conflicts with some of my own plans, etc. Now read the following:

Mr. A. I. Root, Medina, Ohio:

Your postal card of the 26th of last month is received, in which you say, first, that my device has been submitted a good many times. Second, that you don't think it substantial; and third, that it is very expensive. In reply to your first subterfuge, I deny most emphatically that it has ever been submitted to the bee-keepers of America, and no doubt your immense stock of charity will enable you to excuse me for doubting if anybody besides myself ever submitted the same device to A. I. Root. In regard to its strength, I can inform you that I have tested an eight-frame hive with 216 pounds weight without springing the supports the least particle, and I wouldn't be afraid to wager my head they would stand double the above test. As to its expensiveness, I can furnish a machine and directions for making them for \$1.25, whereby any bee-keeper can make his own reversible-frame supports at the enormous cost of two cents per hive. Supposing he had 100 stands of bees, his entire cost would be \$3.25. Now that I have answered your objections, I desire to say a few words in regard to the reasons that prompted you to make them.

In GLEANINGS of Feb. 1st you say, in your closing remarks, "Whatever you send me that I make use of, I am willing to pay for;" and in order to avoid so doing, you wipe me out of existence, by announcing on a postal card that my device is old, unsubstantial, and very expensive, and then go to work and commence manufacturing my identical invention, making it of wire instead of tin. Now, I have the supports made both of wire and tin, but I prefer the tin, and therefore sent you the tin supports.

I supposed when I sent you the model that I was dealing with a Christian gentleman, and therefore didn't expect you to take any undue advantage of me.

Feb. 12, 1885.

The invention above alluded to is simply a projecting arm, hinged so it will turn down out of the way, or turn up at right angles, so as to hang on the rabbet. When reversible frames first came before us, this device was sent over and over; and, in fact, years ago, when I offered \$25.00 for a certain sort of chaff hive, the same thing came repeatedly. It takes eight nails to attach the device to any frame, and I should say the time required to put them on each frame, and drive these eight nails, would be an objection, if the four arms required for each frame were furnished for nothing. Now, friends, these devices have been coming to me for different purposes, required in handling bees, for nearly twenty years. They are labeled and dated, and placed in our attic, for future reference, the inventor's name being on each. When you get up something that you think is ingenious and useful, and wish the benefit of my experience, or wish to know what others have done in that line, I am glad to give it freely, and I do not think I shall ever

make any charge for it. It would lessen our labors a little if you would send along an addressed postal card, for I think a postal card will hold all I want to write on most of the devices that come with every mail. If you think I have passed over your invention too hastily, and wish me to have a clerk search the attic for what has been sent in in the same line, I will do for you, charging you what it costs me. I believe, however, my memory is pretty good; and when an invention has once been placed in my hands, with an explanatory letter, I seldom if ever forget the principal features pertaining to it. If you do not like my way of doing business, let me suggest that you quietly "trade at some other shop," without calling me names, or accusing me of wanting to steal your ideas.

ARRANGING THE HEDDON HIVE FOR THE EXTRACTOR.

SOMETHING ABOUT THE KIND OF LUMBER TO USE FOR HIVE BODIES.

OUR friends will notice in the cut on page 85, that there are strips clear around, about one inch below the top of the hive. I supposed these were intended for an upper story to slip over, as in the old Langstroth hive; but to be sure, I sent for an upper story, arranged as it is to be used for extracting. It came, and with it the following reply from friend Heddon:

Bro. Root:—The cleats around the upper edge of the brood-chamber are designed to help the appearance of the hive, and serve as handles to lift it by. All upper stories (either comb or extracted) do rest on the honey-board, and we object to any telescoping about hives. JAMES HEDDON.

Dowagiac, Mich., Feb. 12, 1885.

Now, with the exception of these strips, the upper story is exactly like the lower one; and if the bottoms were not permanent, they could be used interchangeably, and one piece of the hive could be dispensed with; that is, we make hive bodies, and that is all—no upper or lower story about it. In packing hives close together, these strips are right in the way. Hand-holes, like those we have in the Simplicity hive, would, it seems to me, be just as convenient for handling.—One thing more. Our Simplicity hives which go out by the thousands, and are scattered all over the face of the earth, almost, have been criticised somewhat, but I believe every Simplicity hive we have ever sent out can be used interchangeably with every other one, no matter if you get one from Australia, and another from the Sandwich Islands. Well, I sent to friend Heddon for a hive for a sample. As he did not send an upper story, I sent the second time for one. This upper story sits loosely right over the lower one. When put in place, and frames removed from the lower story, and put in above, the bottoms of the upper frames touch the tops of the lower ones. When placed with the upper story on a honey-board, the bottoms of the frames touch the honey-board. I suppose the lumber of which the upper story is made shrunk, in seasoning, and I presume it is *mainly* because it was made of

what we call whitewood, and we have long since decided that whitewood is entirely unfit for hive bodies, just because it shrinks so as to spoil every thing. We have never found any thing that answered like pine.

BEE CULTURE IN TENNESSEE.

EDITOR GLEANINGS:—Of all the reports and correspondence in GLEANINGS, I see but little from this part of the South, so I will give a little of my experience in bee culture. I have been for about fifteen years a bee-keeper on a small scale, ranging from 10 to 25 colonies, always making it a paying business, getting honey enough to supply my family, and some to sell; and recently finding myself unable to closely follow the pursuits of the farm, and having a natural love for bees, I bought 40 colonies on the 5th of May, 1884, in the Langstroth hive, for which I paid \$200. This, added to my 24 colonies, put me right in the midst of 60 colonies at the commencement of the honey season. So I went to work, and I suppose you know how busy it keeps a fellow to keep it done up in good order. But after a few days of hard work I had 36.00 lbs. of good poplar honey. In June and the early part of July I got about 1000 lbs. of linden honey. I sold all except 500 lbs., at 7 cts. wholesale, so you see I got my money back and all expenses paid, and some money left. I took only about half my linden crop, and well it was; for now it is needed in the combs to give to some colonies that are nearly destitute. The linden crop was very light, on account of excessive rains.

Our principal fall crop here is gathered from a weed known as wireweed, or tanglefoot. On account of drought it was an entire failure in 1884. When the season suits, it yields an enormous crop of honey, blooming from about Sept. 10, until killed by the frost. This plant has been with us but a few years, and has taken possession of nearly all our waste and glady lands. I must mention here that I was sick in October, when my bees needed attention, after the failure of the fall crop, and had five colonies to die for want of attention. I did not allow my bees to increase, having as many as I wanted, and no trade established for bees.

I live in a fine country for bees, the northern portion of Giles County, Tennessee, with but few bees near me. I do not think there are more than fifty colonies in a circle of four miles around me, and they are principally black. I am going to try to Italianize them this year, in order to get rid of black drones. The owners of these are generally men who do not care, and most of them want an overcoat and a bed-quilt over their heads before they venture to open a hive, so you see I have none of the advantages of social and friendly intercourse with intelligent bee-keepers, that some have.

I forgot to say, that the imported queen I got from you through friend W. A. Compton, last August, is doing well. We have had a severe winter up to this time. The bees did not get to fly well in the whole month of January. For two days past it was pleasant, and nearly all the 59 colonies took rye meal freely.

I ran altogether for extracted honey; never used, and, in fact, never saw any of the comb sections. I shall probably have a carp-pond to talk about in the future. J. N. GRIGSBY.

Lynnville, Tennessee, Feb., 1885.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

WATER FOR BEES.

I RECEIVED GLEANINGS and the A B C book in good order, and have been reading where you water your bees, but can not see where you water them as I do mine. I have a trough 12 feet long and 8 inches deep. I fill this about $\frac{3}{4}$ full of clean corn-cobs, then pour on water till it just comes to the top of the cobs. By not having the trough full, the wind does not strike the bees while they are drinking. I think it is better than a board, as the bees seem to like to suck the water out of the cobs. I never had any drowned in this way, nor had any bother by my bees going to my neighbors' horse troughs. I place this trough five rods from my apiary.

I am trying to winter 60 colonies, but do not know how they will come out, as I have them in my cellar.

My trough is V-shaped. I like it better than upright sides, as the bees can run up it and start off better. I sprinkle a little salt at one end of the trough on the cobs, so that they can get it when they choose.

WILLIAM EDEN.

Green Lake, Wis., Feb. 10, 1885.

MY REPORT FOR 1884.

I commenced in the spring with 7 colonies; I increased to 15, and took 250 lbs. of honey. The season was very unfavorable. Old bee-keepers say it was a "bee-famine." I will ask one question. Is it a safe way to feed bees, by pouring sugar syrup into empty combs, and hang them in the hives for the bees?

JAS. E. THARP, SEN.

Harmony, N. C., Feb. 10, 1885.

Friend T., your plan of pouring syrup into combs is a very old one. It is daub, and is liable to start robbing, is perhaps the greatest reason why the plan has not found much favor. There is one thing about it, however, it does not require any feeder to be put in the hive, or to be taken away, and the combs are always all right for the honey when it comes. The syrup must be let fall from a distance, to have it go to the bottom of the cells; and where much feeding is to be done, the combs may be placed in a tub to avoid wasting and spattering, and the syrup poured through a sort of sieve or skimmer, so that it shall fall in many small streams. By this means combs may be filled very rapidly.

HOW TO MAKE BEE-CANDY.

I send you to-day a sample of some bee-candy, and this is the way it is made. Take sugar and water, and boil until it is soft wax, being very careful not to stir after it is dissolved; then set carefully in a cool place until partly cooled, and then stir until it thickens, and take immediately in your hands and work.

A CHEAP WAY OF CONNECTING SECTIONS SO AS TO FORM A RACK OR CRATE.

After looking over Mr. Smith's honey-rack on page 841, December 15, I thought I would give a description of a cheap honey-rack that we use. We use 8-frame hives one foot wide. We got strips of tin cut one foot long and one inch wide; the tinner turns them up to a miter in a machine. Take thin

boards the exact size of the box; set six boxes together with a board at each end; place a strip of tin over each corner, and tack to the board to use on the hive. We lay a thin strip of wood one inch wide across frame to support the corners of the boxes. This arrangement can be used on almost any kind of a hive. When we want to tier them up we take off the boxes and put empty ones under, and reverse the boxes the bees have worked in; putting them on top, there will be no space between the boxes for the bees to get at.

MRS. ORETTA REED.

Washingtonville, Ohio, Dec. 27, 1884.

My friend, your honey-rack is on the plan of the one mentioned on page 162, only you use tin where friend Flory uses wood. The idea is quite an old one, and I do not really know why it was abandoned, for it certainly seems to possess very decided advantages. With the folded tin strips, you are obliged to have a bee-space at the bottom; but it seems to me, as you say, that it would be very much better to have sections come close together in bee-spaces in the second tier, and the same in the third tier when a third tier is used. We can furnish folded tins of the length you mention for 50 cts. per 100, or any desired length at a cost of $\frac{1}{2}$ cent per foot. Folded they nest into each other so as to be shipped in very small space.

WHAT TO DO WITH BEES THAT ARE STARVING IN THE SPRING.

Our bees get water every day that is warm enough for them to fly. There are a great many bees starving in this country. They are in old-fashioned hives, those that are starving. There are a great many black bees in this country. I have had 3 starving swarms come and try to go into my hives in the last three weeks, which makes trouble with the bees. We had one yesterday, which is freezing to death this morning as they lie on the fences and other places, and there is a brisk northern breeze this morning. What would you do in such cases? I have named our apiary "Live-Oak Apiary."

Cedar Valley, Texas.

J. H. MORROW.

Friend M., I should feed the bees, by all means, instead of letting them hang out in the cold to freeze. A very few cents' worth of sugar would fetch them along till plants bloom, and it hardly seems as though there were a locality anywhere where bees will not be worth something after being wintered over. Put them in hives, and give them sugar to their hearts' content, and they will repay you, may be a hundred fold in just a few weeks.

USING A SLATED HONEY-BOARD TO PREVENT THE BEES FROM STICKING DOWN THE CRATE OF SECTION BOXES.

The cut of honey-board on page 47, Jan. No. of GLEANINGS, is nearly the same as the one I used last season. Mine was made out of $\frac{1}{4}$ -inch lumber, cutting the slats with a slitting-gauge. The slats were cut the full length of the board, excepting about an inch and a half of each end, and a $\frac{3}{8}$ -inch square cleat nailed across each end. When the honey-board is on I have a $\frac{3}{8}$ -inch bee-space above and below it. No comb was built between honey-board and sections, but it was fastened down to wide frames.

W. E. THOMPSON.

Ladsonia, Mo., Feb. 14, 1885.

ICHTHYOLOGY—CARP IN TEXAS.

Is that the name? Well, I see so many saying something about carp and carp-ponds, if you will allow me I will "speak my piece." The carp are like a drove of pigs—just give them room to turn around and all is well. A thousand carp in a pond of $\frac{1}{2}$ acre would find ample room, if the water could be kept from three to five feet deep, and all you would have to do would be to feed plenty from May to October.

L. T. Wheeler, Corsicana, Navarro Co., Texas, I am told, has a five-year-old carp that weighed last summer 25 lbs. R. C. Mabry, Blooming Grove, Tex., received from the U. S. Fish Commission, Jan., 1884, seven small carp, 4 months old and 4 inches long, which he put in a small pond of $\frac{1}{2}$ acre. Six of these washed out during the terrible floods last May, and in August he took up the remaining carp and found that it measured 16 inches, only 12 months old. The carp is the best fish I ever saw for our hot-water tanks of Texas. I kept 50 carp, from 8 to 20 inches in length, all through the hot summer of 1884, in a pond not over 50 feet long and 20 feet wide, and a greater portion of the time only 10 to 12 inches deep; and every day they were ready to receive their feed, and would come as quick as that many pigs in a pen.

B. F. CARROLL.

Dresden, Texas, Jan 26, 1885.

A SUGGESTION FOR USING THE HEDDON REVERSIBLE FRAME FOR FRAMES IN COMMON USE.

In regard to the Heddon reversible-frame device, I would suggest stout strong hoop iron for a hanger, bent at top end, say 2 inches at right angles, so as to screw fast to under side of top-bar. Any regular-made frame, projecting ends cut off, will then fit, as the end spaces are wide enough to admit the iron when it would not wood. For proper depth, simply remove bottom-bar, and cut off of end of upright pieces enough to allow bee-space over frames, and nail bottom-bars on again, and you have it.

Baltimore, Md., Feb. 9, 1885.

C. GARWOOD.

KEEPING BEES ON THE ROOF OF A THREE-STORY BUILDING.

I have often thought I would write and give you my experience in bee-keeping. I purchased one colony of Italians in the fall of 1873, and wintered them all right in one of your chaff hives. In the spring they came out a rousing colony; and as I moved to live over the store, and had no other place to put them, I placed them on the roof of the three-story building, which is flat. I increased them to three by artificial swarming, keeping the queens' wings cut, and in the fall I had two good colonies, and one small one having enough bees to cover two frames. I got about 20 lbs. of honey in comb, but I fed them about 20 lbs. of syrup, made from sugar and honey; and up to the present time of writing they are all, so far as I can see, in good condition; in fact, I may say I took a look at the smallest colony, and believe they have somewhat increased. So much for wintering on the roof.

J. E. HOWDEN.

Hamilton, Ontario, Canada, Feb. 10, 1885.

WHO IS THE INVENTOR, AND TO WHOM BELONGS THE HONOR, ETC.?

In the issue for Feb. 1st I gave a description of a chaff winter tenement hive. Since then I have received a letter from Oliver Foster, claiming that he is the inventor of the hive described. While I did not think for one moment that it was an invention

of his, there might be some that would be impressed that it is some of my own origin. I want it strictly understood, that I mean to give honor to whom honor is due; and if it is an invention of his, I hope the bee-keeping fraternity will give him the credit of it. If the chaff tenement hive is an invention of Oliver's, I should like to know it through GLEANINGS. As I supposed it was almost an exact copy of the tenement hive, I thought it was an invention of longer standing. A good many of the bee-keepers are copying, and claiming and publishing in a threatening manner inventions as their own, belonging to others. I hope the fraternity will not countenance it, for we should consider it a dishonorable act.

W. S. DORMAN.

Mechanicsville, Iowa, Feb. 11, 1885.

Friend D., I do not think anybody would gather from your description that you meant it to be understood that you were the inventor of that plan for wintering. I agree with you, that there is getting to be a little too much said about who is the inventor, and to whom does the honor belong? So far as I am concerned, any invention that I have ever made is free to everybody to use, and it does not matter very much whether I get the credit or not. There is one thing, however, that makes it necessary to bring these things up, and that is, when a brother begins to claim this, that, and the other as his own invention, and to threaten others if they use it. Then sometimes it becomes necessary to hunt up the facts. But I think we ought to do it in a kind and Christianlike spirit, remembering that it behooves us to act like those whom Paul mentions as being prompted by that spirit that "thinketh no evil."

REVERSIBLE FRAMES, AND ———.

I send you two reversible-frame attachments. If I have copied yours or Mr. Thompson's, I beg pardon; if not, are they any good? You can let us know through GLEANINGS, and give credit only where it belongs.

Friend Root, I wish to inform you that your "orthodox" rule won't work in the West. Of course, it will in the East, where the fair sex are in the majority; but in Iowa the fair sex are in the minority by about fifty thousand, and some one must stay out in the cold. No doubt the same state of affairs exists in Minnesota; and if it is as cold there as it is here now, it won't take long to freeze out. Bachelors and widowers are like trade-dollars—not the right stamp to be at par. We shall have to insist on female immigration, and lobby a bill through Congress to help us out, if you don't allow girls to come as well as price lists, when both are needed, and you have them idle. I have not had one of your lists later than April 1, 1884, but several of them.

B. F. PASLEY, 13—28.

Zearing, Story Co., Iowa, Feb., 1885.

Your device, friend P., is exactly what we had a little time ago, and, in fact, pretty nearly all the devices that are sent in now are only repetitions of what we have been working on.—In regard to that other matter, I am really afraid I am not competent to advise. As you state it, it is a bigger problem than I had any idea of. If it is really as you state, I do not know but you will have to scrape up a few stamps, and then take a hurried trip out here. May be you have got some relatives that could pave the way a

little, and then make the orthodox plan work all right, after all. We take great pleasure in sending you a price list. Our girls are not as plentiful as price lists yet; and although as a general thing they go everywhere I send them. I am afraid it would be straining my authority a little to direct such a trip as you suggest. But after all, now, may be you are not in the same fix that friend Smith says he is, as related on page 61. May be you are speaking for others.

WEIGHT OF SECTIONS.

On page 82, friend Hutchinson says: "But, suppose a section *does* lack $\frac{1}{2}$ ounce, or even an ounce, of weighing a pound, what is the objection? It will pass for a pound section, and dealers prefer a section that falls short to one that overruns." That may satisfy one man's conscience, and not another's; but to say nothing of the moral question, is it not to the interest of the apiarist, at least so far as the consumers are his own customers, to give full weight, or a trifle over? I believe it is understood that consumers are sometimes of a different mind from dealers.

BURDETT HASSETT.

Howard Center, Iowa, Feb. 10, 1885.

Friend H., I think you misunderstand friend Hutchinson. We always sell our comb honey by the pound; and while it is desirable to have sections weigh exactly a pound, they so seldom do it we always place one on the scales as it is put up. Friend Hutchinson meant to say that dealers prefer to have them run under instead of over, even though they do weigh them up when sold. Shall we not be a little careful about ascribing to others a want of conscience?

LOCATING BEES CLOSE TO THE RAILROAD.

What will the damage be to my apiary to have a railroad come within ten rods of it? It comes so my bees have to cross the track for the greater part of their honey. There will be the smoke and jar, both summer and winter. A man tells me, who has an apiary near the railroad, that it is five minutes before he can see a bee come, after a train passes. I mean an apiary of 100 to 150 swarms.

FRANK H. WHITE.

Stoddard, Vernon Co., Wis., Jan. 20, 1885.

Friend W., I do not believe your bees will be very much annoyed, unless it is on one of the large roads where trains are running almost every hour. If the road runs north and south, there would be less inconvenience from the smoke of the trains if you were on the west side of the track. Our apiary is but a little way from the cars—perhaps 100 yards or more, but we never experience any inconvenience, unless it is when the wind is in the east. So far as the jar is concerned, I do not believe the bees would mind it much, if any; for if it is of daily occurrence they will soon get used to it.

BEE CULTURE IN NEW JERSEY, ETC.

In June I made 6 swarms in a few days. The weather was too hot for them, and I lost one. They did not do much till buckwheat came, then work commenced. The sun got hot, and combs melted down. I took out 9 frames one afternoon, and washed the hive out with water, so that the bees could get in the hive again. I took one hive to the fair, showed it up nicely, and got a special premium

of the small sum of one dollar. How is that for the Hunterdon Co. Fair?

I took of surplus honey, about 150 lbs.; sold about 100 lbs. for \$20, and have five new swarms at present. How is that for a beginner in the bee-trade? I talk bees every day, and tell them it is nonsense to wait till they swarm, when one can make a swarm in 15 minutes. Bee culture is a new business in this part of the country; only four men in this section have frame hives. I tell my friends that I make my own swarms, and they think it impossible. I made 45 hives, and I advertised them, and scattered them almost all over the county, and I have fifty now almost done, and all sold when the season comes. I have about 25 swarms to transfer for my friends in the spring, and I could sell 100 if I had time to make them. We have a factory in the place, and we are cutting hives for King & Aspinwall, of New York. Next September, peaches will be ripe. If you have any spare time, take a trip to Jersey and see us. We ship some nights, 25 cars loaded down.

WM. E. SHEPPARD.

Flemington, New Jersey, Jan. 19, 1885.

HONEY FROM RED CLOVER.

I send you by mail a small sample of red-clover honey. Since I have made the statement that my bees gather honey from red clover, I have had several letters from different ones, wanting to know what the color and flavor are like. A great many think it is not true, that there are bees that will work and gather honey from red clover. I would request you to examine and taste the honey, and give your opinion of it as to its color and flavor. If the sample sent is not quantity enough, I will send a larger package. You will see that this honey has the flavor of bumble-bee honey, and, as you know, the most of the bumble-bees gather their honey from red clover.

F. BOOMHOWER.

Gallupville, N. Y., Dec. 22, 1884.

The sample sent has the flavor of bumble-bee honey very perceptibly, and it is about like the honey called red-clover honey when there happens to be a good flow when red clover is in bloom. It is so little different from ordinary clover honey that one would not be likely to think of the difference unless his attention had been particularly called to it. Any one who has robbed bumble-bees' nests, and tasted of the honey, will readily recall the peculiar flavor when his attention is directed to it.

A SUGGESTION IN REGARD TO SAVING THE MANURE FROM POULTRY.

I have a little interest in your poultry column, and should much prefer dry soil to put under your hen-roosts, to ashes. Ashes will neutralize or dissipate a large portion of the fertilizing property of the manure.

L. C. WHITING.

East Saginaw, Mich., Feb. 4, 1885.

Thank you, friend W. It occurred to me, after that article had gone to press, that I should have advised road dust instead of ashes. If I remember rightly, the crop of corn I raised in my boyhood by use of poultry manure was managed by mixing the ashes and poultry manure just as I planted the corn. As it was immediately covered up, and mixed with the soil to a considerable extent, probably a little loss of ammonia ensued.

THE WAY FRIEND TOMLIN FINALLY GOT HIS TWO QUEENS INTRODUCED.

I commenced bee-keeping last spring, with three colonies of bees; increased to seven; got only 20 lbs. of section honey, for the honey crop was a failure in this locality. I had black bees. But in October I bought two fine Italian queens, untested, of A. D. Stith, of Pleasant Ridge, Ky., both of which proved pure. I had studied the A B C book, and of course I thought I could introduce them without any trouble; but I was mistaken. Having tried all plans in that book for four days, I took the cage from the hive, and shook the bees off. I took four frames filled with brood, and placed in another hive. After three hours I liberated the queen with the young bees, which had hatched out; after 36 hours I took the four frames, queen, and young bees, and placed them in the old hive. They were received with kindness, and did well afterward. I raised five queens, which I gave to my other colonies. All did well, all pure but one. At this date most of them are Italians, and doing well in the Langstroth hive with chaff cushions above.

THOS. S. TOMLIN.

Gardnersville, Ky., Feb. 10, 1885.

USING HEDDON'S CRATE ON CHAFF HIVES.

It strikes me your Hutchinson honey-boards will be "no good" for the chaff hive, unless you make a larger size especially for it. I find it most convenient to use the Heddon case to raise comb honey in the chaff hive. I enlarged it so as to nearly fill the top of the hive, leaving just room enough to insert the fingers to take hold of the handles to take it out. It rests on knife edges of tin, and the bees can not stick it down with propolis, but they will build up from the brood-combs; and if the new honey-boards will prevent this, I certainly want them. My cases hold forty 1½-inch sections, or thirty-two 1¾-inch. The honey-board would need to be about 17 x 20 inches, to go under these cases, or wide frames either, I should say. But a strip of wood will have to be inserted in the upper rabbet, in case wide frames are used to raise them up the proper distance.

CHALON FOWLS.

Oberlin, O., Feb. 13, 1885.

Thanks, friend F., for your suggestions. We can make a larger honey-board for chaff hives, if need be. The brood-chamber to the chaff hive is the same as the brood-chamber to the Simplicity hive, and therefore the same honey-board would cover it; but as this honey-board would necessarily reach above the ledges around the top of the brood-chamber, I do not see how we can manage it nicely without a larger honey-board, as you suggest.

CLIPPING QUEENS' WINGS TO PREVENT THEIR SWARMING.

Although I am not a bee-keeper on a large scale, I will tell you of a little incident that happened this past swarming season. I do not know that it is any thing new, but I never heard of any thing of the kind before. I had one swarm whose queen I clipped the year before (and as that is the only one I had forgotten it). One day as I was going to dinner a large swarm issued from this hive, and I waited for them to eluster; but they all came back in the hive, and then I knew what was the matter. The next day I was obliged to be away (but my wife was at home), and about noon they came out again,

and as she could not move the hive they went back again, and then I watched them for a week after, and they never came out again, but went to work with a will, and stored more surplus than any other swarm I had. Why would that not be a good way to prevent swarming?

P. E. TWISING, 6-10.

Kipton, Ohio., Dec. 29, 1884.

Friend T., the difficulty with your plan is, that the queen will many times go out in the grass or weeds, and get lost; and very likely yours was lost, and they raised a new one. The plan is essentially the same as the one given by Mr. Quinby, years ago. To prevent the queen being lost, he had what he called a "queen yard." For some reason or other, one after another has dropped the process. I do not believe it would pay to lose a laying queen in the swarming season. You might get a good crop of honey with such; but if the queen had been saved with a few bees out of that big swarm, you might have had two crops of honey instead of one.

SETTING BEES OUT FOR A FLY IN FEBRUARY AND MARCH, ETC.

Having very recently subscribed for GLEANINGS, I received my first two numbers last week, and must say that I am highly pleased with their contents, and my little daughter Maud was so delighted with the juvenile department that I fear I shall not get to see each number until she gets through with it hereafter. Well, all right, if it is so. Any thing to induce our children to read.

I have sold the most of my comb honey, being put up in 2-lb. sections, at 25 cts. per lb., and could sell more at the same price if I had it. I have been formerly setting my bees out in February to take a fly; but if it is not necessary it will save considerable work and trouble.

S. R. MORRIS.

Bloomington, Ohio, Feb. 4, 1885.

Friend M., I would leave the bees in the cellar just as long as they are quiet, and seem to be doing well. In our locality I think they will be far better, as a rule, if kept in during the whole month of March, and some seasons through a great part of April. If, however, you can not keep the cellar cool enough to keep them quiet, and if the weather should be favorable, set them out. Our neighbor Rice, who is so successful in cellar wintering, sets his out when they seem to demand it, and then puts them back again, keeping them until pollen is to be gathered, if he can. I would not encourage bees to fly in March, or April either.

THE YUCCA, OR SPANISH BAYONET.

In regard to the yucca, or Spanish bayonet, of which you give an engraving on page 102, you are mistaken when you say that the engraving is the same plant as the one that I sent you a photograph of. The one represented in the cut is of a different species, a native of Arizona; its habits of growth are entirely different from the *Yucca baccata*. The Arizona yucca grows somewhat like the palm-tree, each year adding to its height, with the sharp-pointed leaves all the way up the body. The one shown on page 102 is evidently a young one, and has just started to raise its head above the surface of the ground. This yucca is, however, more useful than the one from which the brushes are taken, as it has been lately discovered that the fiber of the inside of the stalk is very useful for the manufacture of pa-

per, almost equal to parchment, as it is almost impossible to tear it. At our county fair last fall were specimens of this plant, some stalks 12 or 14 inches in diameter, with samples of the pulp, just as it is taken from the stalk, through all the different processes of manufacture, to the finest of paper. Some *lath* were also shown that were made from the pulp. This entire display was taken to New Orleans; and if you wish to take the trouble to look it up, you will find it in the California State Department.

Take one more close look at the plant you have shown, and at the photograph, and you will see that, like your Cal. mountain sage, it "*ain't* right." I was in hopes that you would give your readers a view of this beautiful plant. I am sure that they would all appreciate it, and might help you out in it. I will give \$1.00 toward it.

ABOUT THE WHITE SAGE OF CALIFORNIA.

All that ails these white-sage pictures is, that there are several species that very much resemble each other, and some distinct hybrids. One will send a sample, calling it white sage; then you have a cut made from it, then some one says, "It ain't right," and sends you a specimen that "is right." I have not yet seen a correct representation of the kind we have here in our county. The small branch in the upper right-hand corner of the cut on page 711, Vol. XI., shows the flower all right; but in the large plant, the buttons are too large and prominent, resembling the black sage, or the cross between the white and the black. There is a species that grows south of here, called the "San Diego" sage; another north of here called "Ventura" sage, both different from the native of this county. All claim that the kind that grows in their part of the State is the true white sage. I think that it will be well to wait until the "*doctors*" do agree which is the white sage.

W. W. PLASS.

Duarte, Cal., Feb. 12, 1885.

Friend B., a nice engraving of the plant you send would probably cost fifteen or twenty dollars. I will stand half of it, if there are enough interested to stand the other half, and we will then all have a look at one of your wonderful tropical productions. Some years ago we were told that this plant bore honey by the teacupfuls. It might have been a tablespoonful, however, but it was somewhere along there; and if we get an engraving we want you to tell what you know about the honey from the yucca. We have some growing in our garden; and while they are beautiful flowering plants, we have never seen any bees around them.

A BRIEF NOTE FROM FRIEND WILKIN.

I was quite chagrined because I could not call and see you on my way home, but I could not help it. I got my ears frost-bitten in Kansas, but am here now with my family, amid sunshine and flowers. The winter has been warm, and bees are breeding finely, whilst the fields and mountains look green. I hope you have the honey that my apiarist sent you ere this. It is not with pleasure that I look back at the demoralized state of the extracted-honey market in the east through adulterations.

R. WILKIN.

San Buenaventura, Cal., Jan. 27, 1885.

The honey you mention, friend W., is safe in the lunch-room, and I do not see how your California extracted honey can demor-

alize the market, if it is equal to the lot sent us, unless it created a panic among consumers to see who should get a pitcher full first. By the way, during this cold weather it is a pretty hard matter to get it into a pitcher or other utensil, unless you cut it with a knife, and still it does not candy in the least.

"THESE FISHES," ETC.

I am more than delighted with those articles that have appeared in GLEANINGS on carp and carp culture. It was always a fine sight to me to see a fish swimming in the water, and when, about two years ago, an Ohio paper fell into my hands containing articles on carp I took fire at once, and went out and sat on the fence and studied all over the farm for a site for a pond, but had to give it up. But the fever is running so high now when I learn that these fish grow so quickly, and become so tame, that I believe I will have a pond somehow. I have a spring that affords some water all the year round, and I can catch some off from the barn; and if that will not do I have a supply that I can raise with a wind-mill. I shall begin on a small scale, as we do in bees; then if it works all right we will fix it up nice with evergreens on the west and north sides. Give us all back information quick, for the gravel will have to fly as soon as the frost is out of the ground. I for one have no objections to your articles on poultry, strawberries, or any thing else of home interest. I should prefer something for every issue, for all work and no play makes Jack a dull boy.

A. S. AUSTIN.

Davidson Sta., Mich., Feb. 13, 1885.

Friend A., you can have a carp-pond on any farm where it rains any reasonable length of time, and where the soil is not so sandy and gravelly that water will leach away. Wherever the soil will permit of making a watering-place for cattle, to be supplied by rain water, you can make a carp-pond. A living spring, even though the amount of water be quite small, will be an acquisition to such a place.

CLEANING SMOKER-TUBES.

Let me tell you how I arrange a smoker so the tube can be cleaned quickly, without getting dirt into the bellows. Bore a $\frac{3}{8}$ or $\frac{1}{2}$ inch hole in bottom of bellows, in line with cold-blast tube; close it with a tin slide or button. When tube becomes clogged, turn bellows up, push slide to one side, and punch out dirt with wire.

C. G. KNOWLES, 54-62.

Portland, O., Feb. 9, 1885.

Your plan has often been suggested, and is a good deal used, friend K. We have sometimes thought of making our smokers in the way you mention, but there would be always a liability of leakage of wind where this hole is made in the bellows-board, and the little wires we now send with our smokers make it pretty easy to rake out the tube from the nozzle.

HEDDON'S HONEY-BOARD.

I have just read Jas. Heddon's letter in GLEANINGS, Feb. 1, page 98, in which it seems to me that friend H. lays a good deal of stress on the value of a slatted honey-board that I saw in use on a Langstroth hive six years ago. It was an old hive, and looked as though it might have been in use 8 or 10 years. This board had the space above and below, with the broken joints, all as Mr. Heddon describes.

Michigan City, Ind., Feb. 1, 1885.

A. S. VAIL.

REPORTS ENCOURAGING.

WHAT A HALF-POUND OF BEES DID AFTER JULY 28.

I HAVE thought many times of giving you a little history of the half-pound of bees that I sent to you for about a year ago the 28th of last July. They arrived here so that they commenced work about the 1st of August. The queen proved to be a very prolific one, and nothing but the lateness of the season kept them from swarming. The hive was actually full of bees. Others here said to me that it was the largest swarm of bees they ever saw. But I am going a little too fast. I haven't told you about the honey they made. They filled their hive completely. We took 18 lbs. (8 boxes and one frame). The whole weighed the above amount. I was so proud of my success that I have been afflicted ever since with the same kind of fever that Mrs. Harrison described in GLEANINGS. I've had the antidote tried on me a great many times, but I'm not cured yet. My experience in 1884 beats any thing I have heard of yet. This swarm that I have been telling you of threw off a swarm the 4th of June, a splendid large one, and again the 19th. In July that old queen threw off three swarms. I don't know that one could say they swarmed three times, but she laid the eggs for them all, and they kept on swarming. The last came off the 1st of Sept. I have them now in good condition. They were out for a fly to-day—13 swarms in all, all good large ones but two. These I picked up their queens, and let them go back to their hives. Some of the swarms were large enough to fill a pail when we put them in their hives. Their frames would be filled with honey in two weeks, except the space they used for brood.

One of the swarms went away. They went in their hive all right, but in about two hours they came out and went away. We chased them across fields and pastures, but all to no purpose. They could fly faster than we could run. It seems almost incredible that so many swarms could come from just one queen in so short a time.

I am going to tell you of a swarm that came to us in 1883; that is, what they did last summer. They were a pretty good swarm, but not so large as the other one. I fed them in the spring with syrup and rye and oats ground. During the summer they filled 190 one-pound boxes. I took off, late in the fall, several boxes that were partly filled. I think I can safely say there was 10 lbs. of it, although I did not weigh it. I sold the honey, most of it, for 18 cts. per pound.

Now, Mr. Root, you can put this in your wastebasket, if you like. I just wanted to tell you how well my bees have done. I am looking forward to the time when they will be at work again, with a great deal of pleasure. I love to work with bees. I have often seen poor women trying to get along, perhaps working over the washboard, I always feel as though I wanted to ask them why they don't try bee-keeping. It is easy, and I think pleasant.

MRS. E. E. COLL.

Groveland, Adair Co., Iowa, Jan. 5, 1885.

My friend, I am very glad indeed to get so good a report; but why in the world didn't you tell us how much honey you got in 1884, as the proceeds of that half-pound of bees and queen?—Over 200 lbs. of comb honey from a colony is a pretty good report for any

locality, and I think a good deal of the credit is due to the kind of management you describe in the above.

A GOOD REPORT FROM MICHIGAN.

I commenced with 55 stands; increased to 63; obtained 2500 lbs. of very nice white-clover and basswood honey in one-pound sections. The season was poor in this part of Michigan. J. J. ROE.

Buchanan, Mich., Feb. 11, 1885.

REPORT.

We have a very severe winter. The thermometer is playing between zero and 20 below. On the 3d of February the bees had a good flight; no sign of dysentery then; lest one, which was a late swarm, and a small one at that. I have 50 now, and hope they will pull through all right, for they have plenty of stores yet. They are all on the summer stands, some packed in chaff and forest-leaves, the others protected on top only with leaves in the caps, and I can tell no difference between those packed and those not packed. I will report in the spring, though. J. W. STURWOLD.

Haymond, Ind., Feb. 14, 1885.

FROM 6 TO 16, AND 380 LBS. OF HONEY.

I started bee-keeping last April, with six stands of bees that I bought of a neighbor. I also got one of your A B C books; found it a great help to me, as I had never handled bees before. I got along very well until one night in the first part of June, when some mischievous boys carried one of the best stands about thirty rods away from the apiary, and destroyed the bees, so it reduced me down to five. They increased to 13 stands by natural swarming, and gave me 380 lbs. of extracted honey. I have sold almost all of it for 13 cents per lb.; took them in on the 24th of Nov., all in fine order up to date. This is a rather small report, but I will try to improve from it in the future. E. A. FLIGG.

Oxmead, Can., Jan. 27, 1885.

FROM 50 TO 88, AND 5000 LBS. OF HONEY.

As others are sending in their reports for the past season, I will send mine. I started in last spring with 50 good colonies. They commenced swarming the 10th of June; swarmed rather too much, but I doubled up so that in the fall I had but 38 increase. I have taken off 3000 lbs. of honey in 1-lb. sections, which I sold for from 12½ to 15 cts. per lb. I have 70 colonies in the cellar, 18 in a pit, the first that I ever buried. We have a regular Wisconsin winter—cold, but not changeable. As you know, I got a 100, mill from you that works finely. I am fixed to make my own hives for this season; will do it all by horse-power. I expect you will have to furnish me with sections, at least for this year. My report is not large, but keeps me out of Reports Discouraging. JOHN CLINE.

Fayette, Wis., Feb. 8, 1885.

FROM ONE TO 17, AND 15 LBS. OF HONEY (AND MORE TOO), IN TWO YEARS.

Having noticed in GLEANINGS that your A B C scholars have pretty generally reported to you of their success or failure in regard to bee culture, and as I belong to the A B C class, I will send you my report. Although past fifty, yet quite young in bee culture, and have much to learn, yet I feel well satisfied with my experience thus far, and take great pleasure in taking care of my little friends, the bees, and desire to return my sincere

thanks to you for the plain and practical instruction given in your A B C book, as I knew but very little about bees or the management of them when I began one year ago last spring with one colony of Italians bought of D. E. L'Hommedieu & Bro., of Colo., Iowa, to whom I also feel thankful for some valuable information, and for recommending to me GLEANINGS and your A B C book.

I increased from that one to six, by natural swarming and dividing; the first season I wintered in the cellar, and lost two swarms by insufficient ventilation, and the other four were weak last spring, from which I increased to 17 last summer, and got about 75 lbs. of extracted honey and 60 extra Langstroth frames full of comb, mostly filled with honey, and 15 frames partly filled with comb. Last fall I bought four swarms of bees from parties who had intended to brimstone them, and put them on 40 of my extra combs, which contained honey enough to winter them.

I use two-story ten-frame hives, and brood-frames in both stories; as I was running for increase I did not fall feeding, and think they have plenty of stores to winter. I have them in the cellar, and they are all in good condition.

My report is small, as compared with many others; but as I live in a prairie country, mostly newly settled, and no basswood in reach of my bees, and but little clover, it will account in part for my small report.

W. R. HASLET.

Zealand, Iowa, Feb. 10, 1885.

HONEY IN THE FALL.

I send you my report for 1884, not because it is a big one, but to show that it is not best to be blasted too soon. I am a farmer, and so do not pay very much attention to bees. I commenced the spring of 1884 with 8 colonies in Simplicity hives; wintered on summer stands, mostly blacks, with once in a while one with a yellow band. Willow, maple, apple-tree, etc., bloomed well, and I told the bee-keepers I thought we should have a good season. May 29th there came a frost that froze the ground and killed every thing; even the forest-trees looked as if they had been burned over, and it killed the red-clover. White clover began to come up again, when it became so dry that nothing could grow, and so continued till after July 4. When it began to rain, bees had nothing, not a swarm that I know of, although I did not watch them closely, as I thought they would not get enough to winter on, and were not worth saving. They were killing off their drones in June. Not a basswood-blossom; sumac was killed dead.

After the rains came, the second crop of white clover came up, and weeds and flowers began to bloom freely. About the last of July I looked in the best hive, and saw they were making some surplus. I put on a 26-pound crate, and the middle of August it was filled. I kept putting crates on the hives along, although neighbor S., our apiarist, told me it was not much use, as he never got much surplus in August; but the bees worked right straight along till after October 1. Motherwort, catnip, sweet corn, buckwheat, goldenrod, asters, and all kinds of weeds, bloomed freely. The sumac that was killed by the frost came up the second time, and blossomed about one month later than usual, so that bees did the best in August and September here that they have done for years.

From 8 hives I got 300 lbs. of honey in section

boxes, and might just as well have got 100 lbs. more, if I had put on extra boxes, as they got the hives stowed full, and then stopped for want of room. As it was so hot, and they were so cross, I hated to disturb them; and besides, some that I took off first, the moths got into. Can you tell how to keep the moths out of honey, and will it keep over another year and be as good as new honey?

Honey is worth at Waterbury, where they make watches, 23 cts. a pound at wholesale, if you can sell it; but times are dull. I see by GLEANINGS that many bee-keepers raise tons of honey, and it seems that the consumption does not keep pace with the production.

QUEENS REARED NORTH OR SOUTH—IS THERE ANY DIFFERENCE?

Do you think an Italian queen from the South would be as good for our latitude as one from a colder climate?

H. PERRY.

Southbury, Conn., Jan. 15, 1885.

I am very glad to know you were enterprising enough to keep your eyes open, and take care of the honey when it came, even if it did not come until long after old bee-keepers were in the habit of expecting it. One who expects to succeed must keep watch of things, and never give up as long as warm weather lasts.—I do not think that Italian queens raised in the South will prove materially different from those raised in the North, unless, indeed, the process were carried on for several generations. It might be interesting, however, to investigate this subject. Test queens from Canada side by side with those reared in Florida.

FROM 20 TO 27, AND 120 LBS. OF HONEY.

With order, I send you, according to custom, my report for 1884. Spring count, 20 colonies; increased to 27; made 120 lbs. of honey, over one-third comb, in Gray's sections. As cases seem to be the surplus arrangement for 1885, I shall make all my hives for cases.

D. T. WHEELER.

Rhode River, Md., Feb. 2, 1885.

FROM 2 TO 9, AND 250 LBS. OF HONEY.

Last April I bought 2 colonies of hybrids; artificially swarmed some, and some swarmed naturally. I increased to 9; bought 5 colonies of Italians; last summer I got nothing from the five, but from the others, that is, the 2 colonies of hybrids, I got 250 lbs. of comb honey. I have to feed some candy.

Viroqua, Wis., Jan. 8, 1885.

E. Y. CARR.

FROM 100 TO 137, AND 33 BARRELS OF HONEY.

I started in spring of 1884 with 100 fair colonies; extracted, up to August 29, 33 bbls.; have taken none since. Bees are in good condition; have 137 hives with 23 L. frames each, and 40 nuclei, from 3 to 6 frames each. The latter I have to feed. I shipped 16 bbls. honey to C. F. Muth. Net proceeds, \$404.10; 13 to Hewes, Sharp & Co., St. Louis, not sold; 3 to Memphis, @ 7c.; put up 1 bbl. in glass jars, sold @ 12 $\frac{1}{2}$ to 15c. Total, 33 bbls. Wax, I had about 125 lbs. I hope to see you at New Orleans this spring.

Lakeport, Ark., Jan. 12, 1885.

R. J. ADAMS.

FROM 80 TO 114, AND 300 LBS. OF HONEY.

My report for 1884 is not encouraging. Commenced the season with 80 swarms; went into winter quarters with 114 swarms, all in fair condition for winter; took off 300 lbs. of section boxes filled with honey, and 490 extracted. I had a large supply

of boxes, partially filled, owing to drought. Only for a good run on basswood I should not have had much honey. Clover did not yield much honey here this year. I do my bee-work all alone. I was 68 years old the 27th of last Oct. S. PARDEE.

Volga, Iowa, Jan. 8, 1885.

TOBACCO COLUMN.

QUITTING TOBACCO IN THE SPRING TIME, ETC.

IN regard to smoking, I will say that I have not got to pay for the smoker yet. I have weighed 22½ lbs. more in the summer just past than I ever weighed before. My health has been 500 per cent better than ever before, so you see that it has been a benefit to me to let the pipe lie by. The fight for mastery was sharp and severe for a short time; but by the grace of God I was enabled to conquer, and now I am a free man, and I would say, for the benefit of all smokers, that when you make up your mind to quit, do it in the spring of the year, for then the system is undergoing a change, and the change of season from cold to warm will be a great benefit to you, as a little manual labor then will assist you greatly in throwing the vile stuff from your system with the perspiration, as the pores of the skin are open. I know whereof I speak, for I have been there twice in my lifetime—once for chewing, and once for smoking the vile weed. And now, smokers, if you want to know how your breath and clothes are perfumed, leave off the use of tobacco for 6 months; use it in no form in that time, and at the end of the six months, smell of the breath of a confirmed smoker; and if you are not satisfied to let it alone after that, then I am of the opinion that you have lost all sense of decency. I speak from experience and not from observation. A. H. BRAYMAN.

Waldo, Wis., Dec. 26, 1884.

MIDNIGHT MUSINGS.

It is nine o'clock of the last night of the year, and memory, in her backward flight, dwells on nine o'clock just four years ago, when I emptied, simultaneously, my mouth and pocket of tobacco, and resolved, by God's help and the prayer of friends, never to use it again. How far I have succeeded, you may decide when I tell you I have tasted the weed but once, and that occurred wholly from force of habit. I was receiving for money in one of our drug-stores, when the editor of our town paper walked in for a smoke. At the instant of writing I was asked by him to take a cigar, which, without thinking, I did, and was soon puffing away with all the vigor of bygone days. I believe that smoke made me sicker than the first of my using. I hope to meet you at the Exposition in New Orleans, and many other faces who, from paper association, are almost already known to me. W. F. ROBERTS.

Clinton, La., Dec. 31, 1884.

WHAT A YOUNG MAN THINKS ABOUT TOBACCO.

Mr. Root:—I must write and tell you how much good your Home Papers are doing me as well as others. I read them to two old people that are so situated they can not attend meeting on Sunday. They say a man who can write such good sermons must be a Christian. You don't begin to know what good you are doing through the publication of Our Homes. Go on with the good work, for great must be your reward in heaven.

I must also say a word of encouragement to you about tobacco. I am pleased to think such a man as you are so discourages the use of it, both by example and precept. There are men I know, ministers of the gospel too, who use it, who don't seem to think they are doing much harm either. I should say, if I should say as I thought, that such men had either better give up the use of the filthy weed, or stop preaching. It seems to me that ministers who chew and smoke do more harm by the example they set before others, than good by preaching. Often have I heard men talk about using tobacco who would say such a man uses it, and he is a minister. Don't you see the point, Mr. Root? Perhaps there are young men in almost every neighborhood who think they can't be gentlemen unless they have a cigar stuck in their mouth, if I may use the expression. I am 24 years old, and have never used it in any form. If all I lack is a cigar to make me a gentleman, I never will become one. I might say a great deal more about the evil resulting from the use of tobacco, but I fear I have already wearied your patience by writing you so lengthy an article.

Eddyville, N. Y., Jan. 12, 1885. B. H. BRADLEY.

I have quit smoking. I have used tobacco for 8 years. Now if I am entitled to a smoker, please send me one; and if I ever use it again I will pay you for the smoker. I have 11 colonies of bees; it was not a very good season for bees here. They made a little honey. C. W. BACON.

So. Hamilton, N. Y., Dec. 8, 1884.

ANOTHER FREEMAN.

I smoked tobacco for the last time about a year ago. Now if you please I would like a smoker. We have 3 hives of bees. If I begin smoking again I will pay you for the cost of the smoker.

Collamer, Ohio, Nov. 2, 1884. G. F. CLEVELAND.

CIRCULARS RECEIVED.

C. V. Gross, Pullman Ill., sends us a 4 page list of hives and poultry.

E. T. Lewis & Co., Toledo, O., send out a 10-page list of honey-extractors.

B. F. Carroll, Dresden, Texas, sends us a 4-page list of bees, supplies, etc.

W. S. Cauthen, Pleasant Hill, S. C., sends us his 8-page list of bees, queens, etc.

W. H. Proctor, Fair Haven, Vt., sends out a 4-page price list of bees and queens.

E. M. Hayhurst, Kansas City, Mo., sends us a postal price list of queens and bees.

J. E. Shaver, North River, Va., sends us a one-page list of bee-keepers' supplies.

S. P. Roddy, Mechanicstown, Md., sends us a 4-page list of colonies and nuclei.

A. B. Howe, Council Bluffs, Iowa, sends out a 20-page list of hives, foundation, etc.

J. A. Humason, Vienna, O., issues a neat 4-page price list of chaff and Simplicity hives.

C. W. Costellow, Waterborough, Me., sends us a supplemental price list of hives, etc., for 1885.

F. A. Snell, Millersville, Ill., sends us his price list for 1885. Friend S. makes the Eclipse hive.

J. W. Eckman, Richmond, Texas, sends us a 4-page list of queens and bees. No supplies for sale.

G. F. Williams, New Philadelphia, O., sends out a one-page list of bees, hives, honey, poultry, etc.

S. Valentine & Son, Hagerstown, Md., issue a 20-page list of queens, hives, etc. Albino a specialty.

The American Manufacturing Co., New Carlisle, O., send us a 16-page list of bee-keepers' supplies, bees, queens, etc.

E. Y. Perkins, Jefferson, Ia., has just ordered from our job-rooms a 12-page list of apiarian supplies, bees, and queens.

J. B. La Montagne, Montreal, Canada, sends a very nice 4-page list of all kinds of apiarian supplies. It is printed in the French language.

We have just printed for A. H. Duff, Creighton, O., a 16-page list of apiarian supplies and have several now on hand to print, which we will mention in our next.

D. S. Given & Co., Hoopeston, Illinois, send us a 16-page catalogue relative to the Given foundation-press. Since the death of friend G. his wife has given her personal attention to his affairs.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT.

EDITOR AND PUBLISHER.

MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, MAR. 1, 1885.

And I say unto you, my friends, Be not afraid of them that kill the body, and after that have no more that they can do.
LUKE 12:4.

AFTER laboring hard for two weeks to make myself "useless" among the young people here, Ernest and I start this morning, Feb. 23, for a 12-days' absence at New Orleans.

A CORRECTION.

In neighbor H.'s article on sweet clover, on page 163, he states that it is a *perennial*; the rest of the sentence, however, will show that he meant to say it is a *biennial*.

FIRE.

WE are pained to learn the following from friends Bingham & Hetherington:

We lost our smoker-shop by fire, Monday morning, Feb. 9, 1885, and all its contents. Loss from \$1500 to \$1800, \$400 insurance. In this loss is a lot of knives for our early trade. We are entirely out of knives now, but have a lot making, which will be rushed forward to meet the orders. B. & H.

DISCOUNTS FOR THE FORE PART OF MARCH.

As orders still hold back, and as we are very anxious indeed to get business now, rather than be obliged to run nights a little later, we extend the discount on foundation-mills, foundation, and sections, of 10 per cent until March 15. Sections will also be furnished for \$4.00 per 1000 until the above date, in ten-thousand lots. No discount on this latter offer.

THE A B C OF CARP CULTURE.

THE above is the title of a new book mentioned in last month's editorial; and by the way, friends, if any of you have any special questions you would like answered in regard to it, mail them at once to Milton P. Peirce, 323 Walnut Street, Philadelphia; and if it is something he has not already considered in the work, he will touch upon it, if important.

SECTIONS DOVETAILED ALL AROUND.

WE have so much improved our machinery for making these, that we can make them of basswood at the same prices as the one-piece sections. If made of the white poplar, however, the price is \$1.00 per 1000 extra. One reason why we can furnish these cheaper is, that the new machine uses up all the odds and ends—every piece that is large enough to make a section-blank.

SENDING LETTERS IN PACKAGES OF MERCHANDISE.

ALTHOUGH editors have taken up this subject over and over again, there seem to be a great many people who either do not understand or will not understand that letters must be sent by themselves, and paid for at the rate of letter postage. To-day a small bee-hive containing a model of a reversible-frame device came with a long letter in it, and the

package was so badly tied up that it burst open before it reached us, and so Uncle Sam got hold of our offending friend. If the law should be enforced, it is something like five or ten dollars' fine. Will our reversible-frame friends, as well as all others, please take notice?

PREPARING WAX SHEETS READY FOR ROLLING.

A FRIEND writes us that he has made the great discovery, that if sheets of wax are kept in a tank of warm water, and taken out just as they are put through the mill, they will go through with very little or no starch at all on the rolls. Now, to tell the truth, this is the way we have worked for years past, and we have oblong tin pans made just right to hold a pile of sheets. But come to look at our A B C book, and directions for using the foundation-mill, I can not find that I have ever mentioned it in print. In making foundation during cold weather, this vat, or pan of hot water, is almost a necessity.

OUR 15-CENT STRAWBERRY-BOOK.

WE tried to get it so it would go in our ten-cent library, but could not quite make it. It is the well-known "Strawberry Culturist," by Andrew S. Fuller, and I do not believe there is a better writer on small fruits in general. The book contains 48 pages and 11 illustrations. Price 15 cts.; by mail, 2 cts. more. We make the following extract:

One gentleman in this city, who has no room for a strawberry bed, in fact, he has no garden, nothing but a small yard, which is paved, and upon which the sun shines only a part of the day, yet grows many quarts of fine strawberries every year. His mode is to get plants that have been potted in the fall and all ready for fruiting; these he places upon the sunny side of the pavement in the morning, and moves them in the afternoon upon the other side, leaving them placed upon a platform that is easily and readily moved. The watering and moving are attended to by the children, and by their constant watchfulness and care they learn to love and admire the plants, and when the fruit ripens, each specimen is looked upon as the fruit of their labor, and more highly prized than if bought from the market. Each plant usually gave one quart of fine fruit. I mention this merely to show under what difficult circumstances this beautiful fruit may be grown.

SEEDS FOR THE YEAR 1885.

ALTHOUGH seedsmen are getting to be pretty careful in testing seeds before sending them out, the country-store dealers, and perhaps others, may not be equally careful; that is, if they do not sell out one year, the same seeds may be brought out and offered for sale hereafter. There is a reason for doing this, because many seeds grow as well when three or four years old as when freshly gathered, and it is claimed that some seeds are even better for having age. I believe most of us, however, would prefer to take our chances on seeds carefully raised only a year before. Landreth Sons, of Philadelphia, have made a move in the right direction, by what they call their "cremating" process, and any dealer who purchases seeds of them, and happens to get more than his trade requires, can have the whole lot replaced by fresh seeds by sending a statement, properly witnessed, to the Landreths, that their old seeds have all been burned up, according to orders. Of course, pease, beans, corn, etc., are good to cook or feed to chickens, so we do not need to burn them up. But I do believe, friends, we had better get over the idea of using seed more than a year old, if it can possibly be avoided. If you can not furnish any other, tell your customers so, and make your price according, and then let him take the chances if he chooses. We are just taking measures to put this in practice with our seeds for honey-plants, and every package put up is to have the date, when the seeds were raised, printed on the wrapper.

ADULTERATING HONEY.

I AM quite sure that at least some of the friends are a little too ready to "think evil" in this matter. Some little time ago a very nice specimen of bass-wood honey was sent us, saying a man had been peddling it around, and they were all sure it was adulterated. It was candied white and solid, and of a beautiful flavor. To-day a sample of very fine California white-sage honey comes with a note, inquiring if it is spurious. Very likely the friend who sent it thought something was wrong because it would not candy during our zero weather. The real white-sage honey never candies, even if it gets so cold you have to cut it with a knife. May be the low price at which it is now furnished had also something to do with it. Good nice honey is now sold so low that it will hardly pay to go into the business of making bogus honey.

OUR NEW HYDROMETER, AND THE SPECIFIC GRAVITY OF DIFFERENT KINDS OF HONEY.

I WAS a little surprised the other day, to find that our California honey that is so very thick, and never candies, did not show as great a specific gravity by the hydrometer as our common white-clover honey that is not as thick as the other. It is quite natural to presume that the thicker honey is, the heavier it will be for a certain quantity; but it seems the sage honey has something about it that makes it thick so it runs slowly, without being as heavy as the clover honey; that is, a quart of clover honey weighs more than a quart of California honey, and yet the clover honey pours the easier, both being at the same temperature. The hydrometer sinks to 44 degrees in the clover honey, but to only 43 degrees in the other, and the latter is so thick that, at a temperature of 60 degrees, it takes quite a spell for the hydrometer to get settled.

LARGE PRICES FOR NOVELTIES IN THE WAY OF SEEDS, PLANTS, ETC.

MANY of the agricultural papers have taken up the matter of the continual increase of varieties in seeds and plants, and have commented on the sad fact that many of the novelties are only old things brought up under a new name. The managers of the Experimental Grounds at Columbus, Ohio, have published the results of their test on strawberries; and after making due allowance for differences in soil, etc., the lamentable fact still remains, that a good deal of the blow and puff, accompanied with gorgeous pictures, is only for the purpose of getting people to invest at large prices. Prof. Lazenby has just sent us a report in regard to 28 varieties of strawberries. Only 6 of the 28 are reported worthy of attention. "Big Bob" is summed up briefly, "Unsatisfactory in every way."

Then, again, think of the monopoly on new seeds, new potatoes, and new plants, charging 50 cents for a very few seeds of some improved cauliflower, and half as much for a new sort of celery, etc.! One who by years of pains works out an improvement, ought to have his pay; but, where is there any need for so much pay? A great many of us would like a few plants to test these novelties, but we can not afford to pay 50 cents.

At the time the breeze started up for seeds of spider plant and figwort, there was a chance for making quite a little sum of money by putting them up in high-priced packages, especially for seeds improved by cultivation. But we have, as you know, always furnished seeds of bee-plants, in

five-cent papers. When the article is new and scarce, only a few seeds have been furnished—sometimes, perhaps, not over half a dozen. But half a dozen is, many times, as many as those with small grounds care for. If they want more, of course they can get a larger quantity than a five-cent paper.

Now, I have had for some time a project of furnishing novelties in the way of garden seeds at 5 cents a paper, giving very few seeds where the variety is scarce, and high in price. I think we can manage to put up potatoes in five-cent packages, without trouble; but when it comes to raspberries, strawberries, grapes, etc., it might not be so easy to manage. It would hardly be advisable to sell one plant, because if it should die our customer would be "out," and I never want anybody to pay me money for any thing that does him no sort of good, if it can be possibly avoided. Now, in regard to the five-cent papers, even though cauliflower and celery seed should cost \$5.00 an ounce, I think an ounce can be divided into 100 parts, and then give a customer enough to test the variety. Of course, I should not do anything of this kind in an underhanded way. Henderson's Early Snowball cauliflower is now worth \$5.00 per ounce, or 50 cents for a very small package. White-plume celery is worth just half as much. The seeds are so small that the one-hundredth part of an ounce would answer very well for small seed-growers.

We propose to issue a small catalogue of seeds at 5 cents per packet, in a few days, including seeds of honey-plants as well, and the list we have for years been selling for gardening and horticulture. After having tested the seeds on our grounds, we shall offer for sale as many varieties as we think are worthy of notice by the average gardener of small means; and if you want forty or fifty varieties of pease, beans, and tomatoes, you can find them in the regular seed catalogues—never in ours, I hope.

We have to-day, Feb. 26, 6311 subscribers, or 221 more than last month. Many thanks, dear friends for your kind support.

NOTES AND QUERIES.

GAURA BIENNIS.

THE new honey-plant, *Gaura biennis*, is plentiful in this part of Iowa. It is a weed of recent introduction, having made its first appearance along the railroad eight or nine years ago. It does not thrive on the uplands, but grows to a height of from four to six ft. on the rich alluvial bottom-lands. In the morning a drop of nectar as large as a pinhead may be found in every flower; but by ten o'clock it is evaporated by the heat of the sun. The bees apparently care but little for it, evidently greatly preferring the golden-rod that blossoms at the same time. Farmers need have no fear of the *Gaura*, as it is easily exterminated. Plentiful as it is here, I have never seen a stalk of it in a cultivated field. Z. T. HAWK.

Denison, Crawford Co., Iowa, Feb. 7, 1885.

HOW TO MAKE A FILTER IN A CISTERN.

I have seen a good deal in GLEANINGS lately on how to filter a cistern. I will tell how my filter is made. It is of brick, built in the cistern, laid up with good water-lime cement, just as you would

build a chimney, only smaller. It is 9 by 9 inches inside, and is a little higher than the cistern. The water is all around the chimney, or filter.

The pipe is put down in the filter, and the water filters through the brick. It costs but little. There is no need of coarse gravel or charcoal or iron filings or sponges. It may be asked, "Will the water filter through the brick as fast as needed?" Yes, faster than a cistern pump will draw it.

Dryden, N. Y., Dec. 25, 1884. JOHN McKEEN.

COPYING THE INVENTIONS OF OTHERS, WITHOUT THEIR PERMISSION; LOTTERIES, ETC.

Dear Mr. Editor:—I wish to commend what you say about inventions. We should respect them, whether patented or not. Mr. Heddon has given us a valuable improvement in his honey-board and double bee-space. He should have the control of it. I like, too, what you say as to lotteries. Something for nothing is the bane of the age; it is unrighteous, and no less unpatriotic to stimulate it. A. J. COOK.

Lansing, Mich., Feb. 10, 1885.

FROM 16 TO 26, AND ONLY 51 LBS. OF HONEY.

I started last spring with 16 colonies; increased to 26; this has not been a good season for bees. When the white clover bloomed I thought it would be a good season for honey, as the fields and roadside were literally white with blossoms. From all of my bees I got only fifty pounds honey, poor yield; will try again.

W. D. ANGELL.

Odell, Ill., Dec. 4, 1884.

A CORRECTION IN THE ISSUE OF JANUARY 15.

I see in my report a mistake in GLEANINGS, Jan. 15, page 49, where it reads, "I am now of the opinion that it would have been cheaper to have bought foundation." In the place of the word "foundation," it should read, "to have bought a *machine* from you."

W. D. THARP.

Williamsburgh, N. C., Jan. 28, 1885.

BEES BY THE POUND.

From April 20 to May 20, \$1.00. Dollar queens to go with bees as above, \$1.00 each. After May 20, bees by the pound, 80 cents. 2 frame nuclei, with dollar queen, each \$2.00; 3-frame nuclei, with dollar queen, each \$2.50; 9-frame in Simplicity body, with dollar queen, each, \$5.00. All wired combs. Wishing to go West, I will sell 200 colonies, after May 20, very cheap. Write for prices, stating what is wanted. Edn., heavy, 45c. Light, 55c. Cut as desired. Wax worked at 10 cts. per lb. G. W. GATES, Bartlett, Shelby Co., Tenn.

WANTED AT ONCE.

I will pay \$20 to \$30 and board per month for a man who is thorough in handling bees for comb honey, to work in garden and apiary. In answering, write fully who you are, and what you can and will do. Give reference. None but a reliable worker need apply. I shall answer any person I may select from his reply to this, by telegraph; so do not write unless you mean to come at once.

5d R. J. ADAMS, Lakeport, Chicot Co., Ark.

GIVEN FOUNDATION. Wax worked for a share, or by the pound. Foundation and bees for sale. H. D. BURRELL, Bangor, Van Buren Co., Mich.

WHO WILL BUY? WHO?

80 COLONIES OF ITALIAN BEES for sale by the colony or pound. Simplicity Hives, Frames, Langstroth, 91, 17, 13. Wired frames, combs built from foundation, and are all worker-cells, and straight as boards. The finest lot of bees in the market. Queens and Given foundation for sale. Send for Circular.

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

Such a brisk demand has sprung up for this, and our customers seem to be so much pleased with the goods, we have succeeded in getting another still larger lot, of one of the largest manufacturers of wire cloth in the world. Please bear in mind that the only way in which we can afford to sell it at the very low price of 1 1/2 cts. per sq. ft. is by selling the entire remnant just as it is put up. We have now in stock the following pieces. As fast as it is sold, each piece is crossed out, and the next issue will show what remains.

Width, 8 inches.—3 rolls containing respectively 60, 50, and 60 square feet.

Width 10 inches.—4 rolls, containing respectively 72, 70, 65, and 75 square feet.

Width, 11 inches.—One roll, containing 80 square feet.

Width 12 inches.—2 rolls, containing respectively, 90 and 100 square feet.

Width, 14 inches.—1 roll, containing 80 square feet.

Width, 16 inches.—1 roll containing 130 square feet.

Width, 20 inches.—1 roll, containing 150 square feet.

Width, 25 inches.—2 rolls, containing respectively, 250, and 180 square feet.

Width, 24 inches.—2 rolls, containing respectively, 20 and 30 square feet.

Width, 25 inches.—3 rolls, containing respectively, 53, 142, and 250 square feet.

Width, 26 inches.—7 rolls, containing respectively, 215, 200, 210, 216, 200, 215, and 216 square feet.

Width, 27 inches.—One roll, containing 23 square feet.

Width, 28 inches.—8 rolls, containing respectively, 116, 200, 115, 40, 230, 230, 190, and 364 square feet.

Width, 30 inches.—2 rolls, containing each 25 and 200 sq. ft.

Width, 36 inches.—2 rolls, containing respectively, 270 and 120 square feet.

Width, 38 inches.—4 rolls, containing respectively, 316, 300, 290, and 316 square feet.

Width, 40 inches.—3 rolls, containing respectively, 330, 166, and 150 square feet.

Width, 42 inches.—One roll, containing 245 square feet.

HONEY COLUMN.

CITY MARKETS.

MILWAUKEE.—*Honey.*—The market for honey is quite dull, and values range from 12½¢ to 13¢ for white 1-lb. sections, and possibly, in some cases, if very fine, 14¢ may be obtained. Extracted is slow at 8¢ per lb. *Beeswax*, 28¢ to 35¢ for choice.

March 4, 1885. A. V. BISHOP,
142 West Water St., Milwaukee, Wis.

CLEVELAND.—*Honey.*—The honey market is about the same as last reported; sales very dull, and only the very best in style of crate and color of honey wanted. Best white 1-lb. sections sell at 14¢ to 15¢; second grade, 13¢ to 14¢. Extracted, no sale. *Beeswax*, 28¢ to 30¢.

March 10, 1885. A. C. KENDEL,
115 Ontario St., Cleveland, O.

ST. LOUIS.—*Honey.*—Extracted honey in barrels, very dull, held at 51½¢ to 52¢ for Southern. Northern in kegs, worth more. There is a slightly better demand for comb honey. Choice white clover in one-pound sections, 14¢ to 15½¢. *Beeswax*, not much arriving. Quotable at 26¢ to 30¢.

Feb. 24, 1885. W. T. ANDERSON & CO.,
104 N. Third St., St. Louis, Mo.

CHICAGO.—*Honey.*—The honey market is again lifeless. It is difficult to effect sales, and it can only be done by a case at a time; 10¢ to 15¢ is the range. Extracted dull. *Beeswax*, 30¢. R. A. BURNETT,
March 11, 1885. 161 S. Water St., Chicago, Ill.

DETROIT.—*Honey.*—The honey market is dull at 12½¢ to 13¢ for 1-lb. sections. A. B. WOOD,
Detroit, Mich., March 11, 1885.

I have 3 bbls. of white honey left. They weigh 370 lbs. each, net. I will take 8½ cts. per lb. at Ithaca. Money orders may be sent to P. M. with orders to be delivered when shipping bill is presented. Orders payable at Ithaca, Gratiot Co., Mich. Honey is all from white clover and basswood.
Address F. E. TOWSEND, Newark, Mich.

CONVENTION NOTICES.

The semi-annual meeting of the Boone County Bee-keepers' Association will be held in Lebanon, Ind., April 2, 1885. A general invitation is extended to all.

ORA KNOWLTON, Pres.
S. H. LANE, Sec.

The Northern Indiana and Southern Michigan bee-keepers will hold their next meeting at the Court-House in Goshen, Ind., on Friday, April 3, '85. All bee-keepers are invited to come.

Middlebury, Ind. F. L. PUTT, Sec.

The Tuscarawas County Bee-keepers' Association will meet at New Philadelphia, O., on Thursday, March 26, 1885. We earnestly request all who are in any way interested in bees and bee culture to attend.

GEO. F. WILLIAMS, Sec.
A. A. FRADENBURG, Pres.

The Willamette Valley Bee-keepers' Association will hold their annual meeting at Lafayette, Yamhill Co., Oregon, on the third Wednesday in June. Everybody invited, with request to bring fixtures or any thing that will help to make it a pleasant day.

Newburg, Oregon. CYRUS HASKINS.

The 6th semi-annual meeting of the Western Bee-keepers' Association will be held in Unity Chapel, Felix Street, between 9th and 10th, St. Joseph, Mo., on Thursday and Friday, April 9 and 10, 1885, commencing at 10 A. M. of the 9th. All interested in bee culture are invited to attend and make the meeting as interesting as possible. A full programme will be prepared, and a general good time may be expected.

C. M. CRANDALL, Sec.,
Independence, Mo. A. A. BALDWIN, Pres.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will use notices free of charge, as below. We do this because there is hardly value enough to take queens to pay for buying them up and keeping them in stock, and yet it is often quite an accommodation to those who can not afford higher priced ones.

I have some nice hybrid queens on hand now that I will kill this summer, and it is something I hate to do—that is, kill a queen of any description. I will take 3¢ a piece for them. That will just about pay postage and caging, and the trouble of sending them off.

C. W. HICKS, Fairview, Wash. Co., Md.

QUEENS FOR SALE.—Hybrid queens, 5¢ each; black queens, 25¢ each, from June 1 to Oct. 1. Safe arrival guaranteed.

R. H. BAILEY,
7-11db P. O. Box 81, Ausable Forks, Essex Co., N. Y.

I have 6 hybrid and 6 black queens to dispose of, 60 and 2¢ each. Safe arrival guaranteed.

HENRY WRIGHT, Selma, Dallas Co., Ala.

I have some hybrids the friends can have at 50 cts. each, if they apply soon.

D. MCKENZIE, Carrollton, N. O., La.

I have 20 black queens for sale at 50¢ each, 200¢.

A. W. BRYAN, San Marcos, Hays Co., Texas.

QUEENS in MARCH.

We are prepared to fill orders for untested queens during March at \$1.25 each.

J. M. KILLBOUGH & CO.,
San Marcos, Hays Co., Texas.

I have untested queens for sale in March, April, and May.

NELLIE ADAMS,
Sorrento, Orange Co., Florida.

DADANT'S FOUNDATION FACTORY. WHOLESALE AND RETAIL. See advertisement in another column.

Waterbury Watches, Old Series.

In order to close out the old ones, we will sell the following watches while they last, as follows:

Five watches, first series, in good running order, but some of the cases look a little shabby. Mailed postpaid for \$1.50 each. This gives you a timepiece, without any particular regard to looks, for the small sum of only \$1.50.

Of series A we have five dozen. These have nickel cases, and are in good running order. The objectionable feature is, that they have an opening in the dial. We will send these for \$2.00 each.

Of series B, we have 31 watches left. These are equal to any in appearance and time-keeping qualities, only they have not some of the more recent improvements. So long as they last, \$2.50. I have carried all the above, to test them myself individually; and any one of them that does not keep time when you get it may be returned at my expense.

A. J. ROOT, Medina, Ohio.

DIXON & DILLON,

Parrish, Franklin Co., Illinois.

WIDE TOP-BARS, ETC.

ALSO SOME MATTERS CONNECTED WITH THE CONSTRUCTION OF HIVES GENERALLY.

I HAVE just read Bro. Alley's article on the above subject. I once thought just as Bro. A. now thinks. Nearly all my bee-keeping friends used $\frac{1}{2}$ -wide top-bars. I was fresh from Father Langstroth's book. I used $1\frac{1}{2}$ -wide top-bars, as that book advised. I discussed much with my friends about it. I told them that narrowing the space between the bars tended to dissuade the bees from building brace-combs therein. That was the way I understood it. I had used the one width only. These friends claimed just the reverse. I saw that their hives compared with mine proved their side of the argument, but I thought there must be some other factor to influence the matter in *this* case. I knew that bees were less apt to build comb in small than in large spaces, behind the end-bars, and other places. My theory was all the time right; but the facts were all the time against me.

Well, I cut down to 1-16. I was glad I did. Then to one inch, and I liked that better; then to $\frac{1}{2}$, and I like that better still; and I own up, slowly but surely, beaten. It is just so with the slats of honey-boards; as I said in a late article, the queen-excluding spaces are much worse filled with comb than those $\frac{3}{4}$ wide. Experience will do for you what it has for me,—settle it to your satisfaction.

Bro. Hatch is in error, if he thinks that I meant to claim that the bees would not build brace-combs between the *brood-frames* and the slats of the honey-board. Of course, they will; and if the honey-board is not there, these same brace-combs will be built to the sections, or wide frames, and this is just why

we want it there. The idea I meant to convey was, that they would build between the *sections* and honey-board, but very little if any. Whenever we have contracted to five combs it brought the spaces just exactly over each other, and then we had to shove the honey-board sidewise on the hive, or up came the brace-combs, as the spaces no longer "broke joints" with each other. What Bro. Hatch says about moral patent is too true. The honest pay while the dishonest go free.

Bro. Flory, in his article on page 162, seems to think we use a honey-board to each case, while none is needed except just over the brood-frames. Now, Bro. Root, we make our hives and extracting-supers of pine. Our supers were all at the apiary; but the one we sent you was a very old one that had been mislaid about our shop up here in town. I knew it was a little scant, but thought it would do for a sample (we charged nothing for it), and thought you would overlook that. We talked about that here when we packed it. Pine is best about shrinking; but whitewood is best to hold paint. You have not described the super correctly. It has no raves, or cleats, around it like the hive. It is $\frac{1}{2}$ inch shallower than the hive. The frames (the same as used below) rest flush with the bottom, the bee-space below being in this same honey-board. I know wabbled slots are out of the way, but not as good a hand-hold as the large end-cleats, and we make hives more to use than to ship. It is, however, of not so much importance how the super is made. Let it be the same length and width of the brood-chamber, and one-half inch shallower, or just so the frames rest even with its bottom, and take the same kind and number of frames that the brood-chamber does, which, by extended experi-

ment, I have found better than to have any different number or style of frames for the upper story.

Bro. Garwood (page 170) suggests a change in my reversible frame. One year ago I made 8000 of them. Please figure the difference in cost, when his "hoop iron" and "screws" are added. I used about seven dollars' worth of wire nails, two to hinge each frame. I also figured on screws, and they were going to cost about \$25.00.

I will close by returning thanks to you for what you said about the honey I sent you. It is bringing me lots of orders. I thought it good, and meant to give "big weight." Also to Prof. Cook for his sentence on page 179, both for the words of praise for me, and sound logic and morals in a general sense.

Dowagiac, Mich.

JAMES HEDDON.

It seems to me you have made a little mistake in figuring on screws, friend H. Sixteen thousand 3-inch screws will cost only about \$8.00 instead of \$25.00. In fact, we can furnish them for that, and I think I should prefer screws for reversible frames to wire nails. The idea is, that the hoop iron will permit us to use the frames we are already using, while your arrangement does not. A top-bar made of a strip of folded tin would also fix the depth pretty nearly right; but after figuring on it, I decided it would get bent or doubled up. I suppose the wooden bars for the frame to turn on will be a little cheaper than the hoop iron, but the labor of attaching the hoop iron to the top-bar would be more than the value of the material. My experience agrees with yours in the width of top-bars.

BEES—TEMPERATURE INSIDE CLUSTER.

DO BEES HIBERNATE?

IN talking over W. F. Clarke's hibernating theory some three months ago, a friend remarked: "Would you not like to know just the temperature maintained in the inside of a cluster of bees of sufficient strength to occupy five or more spaces between the combs?" I replied, that I did not believe that bees ever hibernate, according to the general meaning of that word; for Quinby tells us, in his "Mysteries of Bee-keeping," that the bees in the inside of the cluster in cold weather, are as lively as in summer, while those on the outside are somewhat stiffened with the cold, which I had found to be so; hence the temperature in the center of a cluster of bees must be about the same as our summer temperature.

Soon after this I noticed these words in the *American Apiculturist*: "Not one of this class can tell us any thing reliable about the winter temperature of the bee-hive," the "this class" referring to entomologists. I thought, if no one knew what the inside temperature of the bee-hive was, that it was time we did. I therefore instituted a search through all the volumes of GLEANINGS, by means of its copious index, only to find these words in Vol. IV., page 10: "Now, when bees are massed together in a cluster they keep up an animal heat that keeps the whole cluster above freezing." If there is any thing else in all of the 13 volumes, bearing on the subject, I failed to find it. Having a desire to know, now kindled into enthusiasm. I procured, at a high price, the best self-registering spirit ther-

mometer possible, and soon had it in the center of a good colony of bees which occupied a sphere of about 8 inches in diameter. As I could not get the case holding the thermometer between the combs, I slipped the graduated part with the spirit glasses from the case, and, by means of a rubber band and a bent wire, fixed it so I could suspend it where I wished. I found that even now I must spread the frames in the hive, in order that this graduated part might go in the hive, for there must be a space of $\frac{3}{4}$ inch between combs for it to slide down into.

As zero weather has been the order of the day for the past six weeks, I disliked to disturb the bees; but I soon saw that this zero weather was just the time for the test, if I would have it reliable. I hesitated no longer, but pried apart the frames, which, in the cold, went apart with a snap, which soon caused a fuss to be made; and in spite of all I could do (I had no smoker with me) many bees were lost by darting out as the center of the cluster was disturbed, which showed that they were far from hibernating; although half a minute before, the colony hardly gave signs of life. This thermometer registers cold as well as heat, by having two spirit balls and two steel bars, or registers. These registers, when placed in the hive, were set where the temperature stood in my coat-pocket in which I carried the thermometer, which was about 45°, when it was placed in the hive at 4 o'clock P.M. Upon taking it out the next morning (again losing bees which were drawn out by the thermometer) I found I had only a satisfactory register of the heat the colony had attained in the disturbance (which was 87°); for as soon as I drew it out of the cluster, and before I could brush the bees off from it, the mercury was forced down on the cold side several degrees. I now took it to the stove and left it till the heat side showed 106°, with a corresponding degree noted on the cold side. I now drew down the steel register on the cold side by means of a magnet provided with each thermometer, and then wrapped it in a warmed cloth, when, as soon as possible, it was again placed in the same colony. During the afternoon the weather became severe, and continued so for five days, during which time the mercury outside went as low as 16° below zero. When the storm abated, the thermometer was taken out, when I found that the coldest point reached in the cluster during those five severe days was 65° above zero. In like manner I kept experimenting on several colonies until I found that the average temperature of a good colony of bees in the middle of the cluster is 64° when the mercury is at zero outside the hive, and that, for every 15° of change (outside) from this point, the change in the cluster is one degree. Thus: 16° below zero, 63°; zero gave 64°; 15° above gave 65°, and 28° above (the highest it has been during my experiments) gave 66° in cluster. All the colonies were in chaff-packed hives, with sawdust cushion 4 inches thick over top of hive, and nearly covering the chaff on all sides. Some of the colonies had honey as stores, and some sugar syrup; but I could see no difference in heat in favor of either one.

I next placed this thermometer within half an inch of the outside of the cluster, both at the top and at the sides, and found that the temperature varied here from 46° to 52°, according to place and coldness of the weather. At one time it touched 45°, thus showing that, just outside of the stiffened, or hibernating bees, as Mr. Clarke would call them,

the temperature is the same as that at which bees will barely fly in May. Unless my bees have a chance to fly soon, the prospect is that these experiments will cost me something; for some of the colonies thus treated are getting quite uneasy, and show signs of the bee diarrhoea.

By one experiment I find that the lowest temperature in a diseased colony is 75°. I believe them to be rearing brood, but can not well open the hive, on account of the steady cold. From the above I think all will see that it is impossible for bees to hibernate when they must burn honey enough to warm a temperature of 16° below zero to 6.° above. This makes it also plain why it takes less honey in the cellar to maintain 64° to 67° of heat in the cluster, where that of the outside never goes lower than 47°.

I may next winter take notes regarding these inside the cellar; but as I have not been inside the bee-cellar since Jan. 13, I shall not try the experiment this winter. G. M. DOOLITTLE.

Borodino, N. Y., Feb. 28, 1885.

Thanks, friend D., for the positive facts you give in this matter; but I do not quite see that you have settled it after all, for you say the cluster was disturbed by putting in the thermometer, and without a doubt the temperature rose rapidly as soon as you began to disturb them. I fear you skipped over something in the back volumes of GLEANINGS coming pretty near to this point. It is where I spoke of pushing my hand under the cushion, just over the cluster of bees, to see if they were alive. In the house apiary I used to do this often, and it seemed like putting one's hand under an old hen while she is sitting. I think I described it something that way. Now, had you pushed your thermometer right over the cluster, a thin sheet of cotton or enamel cloth only intervening between the bees and the thermometer, it seems to me you would have accomplished almost as much, as the heat rises, and would keep the cushion and all above it pretty nearly, I think, up to the temperature of the cluster. But even this disturbance would probably elevate the temperature of the cluster.

Now a word in defense of friend Clarke's theory. Sometimes a cluster of bees is warm and lively, and at other times it is not so lively. Quite a number of us have at some time or other pulled the combs out of the hive, thinking the bees were dead; but we finally decided they were only asleep, or in a sort of dormant state; for after a while they woke up and could sting as well as any bees. When we find them thus, they are so knotted together that it seems to me next to impossible they could stir enough to move even a leg or a wing. They are packed into cells, and squeezed together in combs, until one would never believe so large a number of bees could be put into so small a compass. I remember one spring when a certain hive did not come out to fly, while the rest did. I looked in and decided that the bees were gone; the combs were clean, and full of stores, and I had commenced taking them out, until, down in one corner of the hive, I found a ball of bees about the size of a large apple. When this ball unrolled, or unfolded, they filled the hive pretty tolerably.

They were not up against the cushion at all, but down toward the bottom-board, and there was frost all through the hive, except close up to this cluster. They made no sound, that I could perceive, and no movement, until I pulled them to pieces, and let the sun down on them; and it seemed, when taking the combs out, as if I should tear them limb from limb, so tightly were they tied up in their winter nap. I presume this thing is familiar with hundreds of our readers; and I believe that most will agree that bees, when knotted up in this manner, always winter splendidly. I have no idea that the temperature of this ball was as low as the freezing-point; but it seems to me it might be down about the same as the bear and the woodchuck when they lay themselves away. I have for years supposed they sometimes go into this semi-dormant condition, and at other times that they do not; or I have thought that perhaps some colonies had a fashion of going to sleep, and sleeping for weeks or months in this way. I do not believe we need now many theories on the subject, but we do need facts; and I for one should like to have my bees winter in these little tight balls; at least, it seems to me that is what we want.

FROM BURMAH.

The *Apis dorsata* Heard From Again.

HOW FRIEND BUNKER SUCCEEDS WITH BEES.

BROTHER BROT: It is very kind of you to say for my poor notes to you, and to send your valuable magazine free at the same time. I really don't expect pay, nor ask it. I shall be most glad if I can in any way add a little to the sum total of bee-knowledge in the world, and at the same time afford myself a most delightful study in natural history.

I am off to-morrow morning for a long preaching tour among the wild Padang Karens, so I just write to say that I shall take much pleasure in studying the *Apis dorsata*. I have a large church near by (20 miles off), which has in its possession scores of swarms of this bee. I can get every opportunity to study the bee, and will do so. I think I will get a sheet of brood, and put it into a swarm of common bees, and see what will become of it. I have now five swarms, all doing well. One swarm has trebled in size in two months, under stimulative feeding. I am keeping careful notes, and shall be glad to report progress, but don't think you must pay me for my writings. I want to help, not only for the good of others, but for myself and my people. The study of bees is a fascinating one, even in the very small beginning I have made.

My bees are of two kinds, quite distinct. One is small, 6½ cells to the inch, brown, wings give off colors in the sunlight, gentle, and active. The second are larger, 6 cells to the inch, black, active, and aggressive. They went to robbing a stronger swarm the second day after being transferred. I have not had them long enough to tell all the differences yet, but am studying them, and will report in due time.

I am now going out as a fisher-of men, and shall leave bees behind. I hope I may catch some souls. The fields are white for the harvest. Oh, where are the reapers? One man for 77 districts and stations,

and for thousands of heathen! Who is sufficient for these things? But God can do his will, even with a feeble instrumentality. A. BUNKER.

Toungoo, Burmah, Dec. 15, 1884.

Why, friend B., is it really a fact that you are right in the neighborhood of the *Apis dorsata*? Do you mean that your people belonging to that church have the *Apis dorsata* in the trees, or have they got them in hives? In any event, you seem to be a providence to the bee-keepers of the world. Our short-hand writer suggests that the solution of this difficult question of getting hold of this race of bees is to come through our missionaries, as have many of the greatest blessings the world has ever received from lands hitherto unreached by the gospel. May God bless your efforts in working that great field where laborers are so few!

"THE SILVER LINING"—A BOOM IN CUBA.

600 LBS. OF HONEY FROM A SINGLE COLONY IN ONE SEASON, WITH THE AID OF THE HOLY-LAND BEES.

THE cloud is seldom so dark that it has not a silver lining; but three months ago it seemed impossible that there could be much light behind the gloom of despondency and doubt that hung over our future prospects for a favorable report of our first year's work upon this wave-washed little spot of land here in the middle of the ocean. But we had "builded better than we knew;" for when the first day of December opened we had 113 colonies of bees left from the summer's wreck; and with the advent of December came the bellflower with all its hoarded stores of sweetness, and such storing of honey as our 113 colonies in a weak condition did for 61 days was seldom if ever seen, I think. During that time they stored 49,125 lbs., making an average of 355 lbs. to the colony, with 10 lbs. to spare.

Good and grand as this average is, it is not what is possible or probable in Cuba, with colonies in good condition when the harvest opens; but as I told you in a former article, we did not know how to manage our bees for a winter honey-flow. When the harvest began we had perhaps 25 colonies in fair condition to store honey, and we weighed the honey from one of these as it was thrown out, which amounted to 625 lbs. While I know that even 600 lbs. is a "terrible" yield per colony, for a large apiary, yet with bees in such condition as any Northern bee-keeper would have his bees in for a June or July harvest, 500 lbs. to the colony I do not think would be putting the figures out of reach or too high, for this crop of honey that we have just harvested is to be credited to Cuba's resources in that direction, not to our management, for the latter has been one succession of blunders, because, to manage bees for a winter flow, is as different as the management for a spring and summer flow as a locomotive is different from a prairie schooner. And then the strain of bees has all to do with the result. The Italian bee will not do for Cuba. Why? Listen and see. The Italian is credited with having a great deal of sense, and their judgment in that line stands them in a good light in the North; for as soon as our dearth of honey begins the first of July, the Italians stop laying,

and for four months they lay hardly enough to furnish bees to protect the combs from the moth; then when the honey dearth is over, the winter months are upon them; then they want to go into winter quarters; and the first day of December, with the grandest honey-flow in the world, finds the Italians with no bees to gather it.

Now this 19th day of February they are getting strong; but of what use are they now? Our white-honey flow is gone, and for the next four months they will breed and swarm to their hearts' content; but, to what purpose? To be able to sleep through the next December and January honey-flow.

Well, after what experience I had had with the Holy-Lands in California, I concluded to try them in Cuba. So we ordered a breeding queen from D. A. Jones; but when her bees came out they were so very cross, that we thought it would be impossible to handle them during a surplus season, so did not raise more than 25 queens from her; but there is where we fooled our own selves, for the bees reared from the daughters of the Jones queen were as easy to handle as the Italians or blacks; and for honey-gathering they stood over them all as a class. Why? because they had bees to gather it. And why did they have the bees? Because, during the fall months (even when there was no honey coming in) the queens kept laying; and when at last the clouds did lift, there was the silver lining. The Holy-Lands were ready for business. Now, friend Root, can you see why the Italians are not good for the Cuban bee-keeper? Again, I say, all this we had to learn; but if "fortune favors the brave," look out next winter. When, after two months of steady hard work, extracting every day, the Cuban bee-keeper finally "rests from his labors," he not only has a good crop of honey in number of pounds, but he has as fine a crop of honey in quality as the world can produce. Cuba can, in a few years, "without fear or favor," challenge the civilized world to beat her in quantity or quality. He that thinks this is boasting, let him watch the progress and returns from this industry for the next ten years. But it must of necessity go a little slow for the first years, for the art of managing bees for winter work must be fully learned, and I am sure it can be; then the coast is clear, for the honey is here—there is no doubt of that.

One word now to my brother bee-keepers of the North, about overproduction, and I am done. Let no one who keeps bees in the U. S. fear that Cuban honey thrown upon their markets will ever reduce the price of their honey one farthing; for such honey as is produced here by the use of the extractor will not go to the U. S.—but a very small per cent at least, but will find a ready market in the old countries, where it will be used principally for medicinal purposes. So, brother bee-keepers, go ahead and produce all the first-class honey you can; it will sell.

A. W. OSBURN.

San Miguel, Cuba, W. I., Feb. 19, 1885.

Friend O., the above sounds something like it; and from what experience I have had with the Holy-Lands and Italians, I can readily understand how the result you mention is possible. The Holy-Lands would go to work and raise bees right straight along, drought or no drought, you may depend on it; and when the time comes to gather honey, they would probably be "up and dressed;" and the next move will be, not for Cal-

ifornia, nor even for friend Hart's vicinity down in Florida, but straight for the island of Cuba. Well, well, what next?

PROMINENT BEE-KEEPERS.

Our Friend Wm. Muth-Rasmussen, of the Pacific Coast.

HOW HE LOOKS AMONG HIS FRIENDS.

OUR friend whom we mention above, and whose picture we give below, has been for many years a sort of representative man among California bee-keepers. We shall not attempt to give much of a biography, for he very kindly furnishes us the following letter:

Several years ago you were kind enough to send me, at my request, your photograph. Please accept hereby mine in return. I do not pretend to be a "prominent" bee-keeper, nor do I belong to the very extensive ones, having seldom exceeded over 100 colonies at any one time. But I claim to be a bee-keeper from the bottom of my heart to the very tips of my fingers. About 16 years ago I was attacked by the bee-fever, and have suffered from the complaint ever since.

WM. MUTH-RASMUSSEN.

By way of a "biography," I will add that I am a Dane by birth, and, after receiving a good college education, I learned the trade of machinist. In 1869 I came to this State, and, finding business very dull in my own trade, I engaged to work a summer for a bee-keeper in Los Angeles Co. Well, I found that I liked the business, could stand the stings, etc., and I have stayed with it ever since. After living at Los Angeles for ten years I moved to Inyo Co., where I have now been located during the last five years; have for several years been Vice-President for California, of the North-American Bee-Keepers' Society, though I do not regard that as owing to my "prominency," but simply to the fact

that I occasionally appear as a contributor to the bee-papers. During the last year I have been engaged to furnish regular articles for the bee-keepers' department of the *Pacific Rural Press*.

I send this picture, principally in the hope that other bee-keepers, whom I have known for years through their writings, may follow my example, and thus not only aid you in keeping up this department of GLEANINGS, but give us all the pleasure of looking at each other's faces, though we may never become personally acquainted.

By the way, friend Root, why don't you give us the picture of Doolittle, James Heddon, Mrs. Harrison, and other well-known and appreciated writers, whom you probably have in your "bee-keepers' medley," and could transfer into GLEANINGS?

WM. MUTH-RASMUSSEN.

Independence, Inyo Co., Cal., Jan. 26, 1885.

Friend M., we would have given Doolittle's picture long ago, but he would not let us have it; said he had not time to go to the artist's and have it taken, or something like that. Mrs. Harrison sent us her picture, which you will find on page 275 of the A B C book, and in GLEANINGS, page 123, 1882. Since you mention it, it occurs to us that Heddon's picture would come in very nicely at this crisis; and so, friend H., straighten up a bit, rub the cobwebs out of your eyes, and send us your picture, and we will tell our engraver to do his level best. If you are busy just now, send us some picture you had taken some other time. It will be like you, no doubt.

"THINKETH NO EVIL."

I HAVE just read GLEANINGS for Feb. 15. In reply to Bro. Heddon, I will say that I meant page 2 instead of 20. I can not say whether the mistake is mine or the printer's, nor what year the price list is for, since there is no date on it. I presume Bro. H. is right when he says he meant the 1 $\frac{1}{2}$ -inch sections would not weigh a pound when separators were used, but he says so only by inference.

I had not received his price list for 1885 when my letter to friend Hutchinson was written, so the part concerning the making crates for 8 cts. does not count; but the next hit, where he gives rather a broad hint on my veracity—did you ever? What will come next? I have not the pleasure of personal acquaintance with brother H. or I should feel rather hurt at that; but as it is, we will let it pass as a "scientific pleasantry." I did think of these moral points, Bro. H., and that is just what set me to writing.

C. A. HATCH.

Ithaca, Wis., Feb. 16, 1885.

Thank you, friend H. I should be very sorry indeed to see any thing unpleasant between two good men like Hatch and Heddon, and why should we not all remember that it is a very safe thing to do, to put things *very* mildly? It almost always transpires, when you come to get down to the facts, that it was a misunderstanding, instead of any *purposed* evil. Let us call it "scientific pleasantry," and drop it, and it seems to me there might be a good many more things that we might put under that head.

PURE GERMAN CARP.

DIRECTIONS AND INSTRUCTIONS.

FRIENDS, little did I think, when I sent that piece to be published in GLEANINGS, that it would require half my time (would I do it) to answer at length all letters of inquiry, therefore I have concluded to have them inserted in GLEANINGS. By the way, I will say, from the amount of letters received from all parts of the country, that GLEANINGS must be one among the best papers to advertise in now printed. WHERE TO BUILD PONDS, AND WHO CAN HAVE THEM.

The best site for a pond is where it can be fed by living springs, either hard or soft water, which makes very little difference. If you have not this, a pond built in a hollow, or on a running stream, by throwing up levees, or dams, in order to raise the water at the mouth of the ditch.

If you have a long ditch, or one running from a spring or springs, it will make a good pond by digging out at the mouth of said ditch, sinking it lower than the ditch. If you have none of these, sink a hole in the ground, and cement it, and it will do.

HOW TO BUILD A POND.

Where you have a good spring, select your place below the spring; and should you wish to lead water by pipe, use nothing smaller than 2-inch. Stake off the size of the pond; no difference if you have one, two, or three banks. Where you want to throw up the levee in order to make the pond, you want to cut what is called a muck ditch. This is done by cutting a ditch 18 inches wide, then throw it out as deep as the soil or gravel extends, then plow the best clay you have about the place, and scrape it into the ditch. We will suppose your place has a bank on the west and one on the north, then you will have to make levees on the east and south, having your muck ditch cut coming up the bank as far as the levee is to be made, but cut same depth as at the other part. Say it is two feet deep in the main, bring it the same depth up the slope. You say, "Why the ditch?" Well, it is impossible to make a joint that will not leak without it. Now you commence scraping, drawing the clay to fill the ditch, say at the west end, driving your team over the ditch every time; this packs it down, and makes it water-tight. After you have the levee two or three feet high, then you can use any kind of dirt to complete it. If you make the levee seven or eight feet high, it ought to be 10 or 12 feet at base. Should the bottom of pond be loam, sand, or gravel, put in three or four inches of good clay, then feed hogs in it a week or two; this will make it water-tight.

In case you build a pond fed by a stream, let in the water by tile or pipe, throwing up levee or dam above as well as below, then cut a ditch around the pond to carry off all surface water. If your pond were in a hollow, and a long slope from both sides, it will be necessary to cut a ditch on both sides, two or three feet above the water, in order to carry off all surface water, and also the overflow of stream.

Should you wish to construct a pond at the mouth of tile ditch, you will proceed as above, except you will have to throw out the dirt in order to make depth, as it will not do to raise the water above the mouth of tile. In case you want to make a pond or tank on a small scale, select the place; and if you have running water to fill it, use pipe or tile to lead

it. If you have no running water, and have a never-failing well, use a wind-pump, which will furnish all water needed. I know of one tank, size 16 feet long, 8 feet wide, and 6 feet deep, dug square, and cemented, fed by a wind-pump, which has proved a success on carp-growing, but not on hatching; but it pays to buy small carp, and stock the tank, feeding them the refuse of the table. I find, since my first introduction to the business, that there are a great many natural ponds in the country, which it is not necessary to speak of, only to say that carp will do well in them, if directions are complied with.

OUTLETS.

These are made according to the amount of water flowing in and out of the pond. If it is fed by a spring or ditch, and no surface water in time of rain, a small pipe or box put in at high-water mark will do; but if fed by stream, or a good deal of surface water, an apron will be required, which is made by taking matched planks, sawing them from 4 to 6 feet long, setting them perpendicularly, making them fit tight together. This must be in the center of levee, lengthwise, letting the top come up to high-water mark, then fill and ram solid, making the clay even with top of plank. Now make your apron the same width of upright, taking care to extend it over the levee to prevent wash. Nail it down; put side-board on, and fill around with clay. Use a wire screen, put on a frame for all outlets, then you can remove and clean when it becomes clogged up.

TO DRAIN A POND.

To do this successfully is something that I have failed to accomplish to my entire satisfaction. In building a pond you put in a box or pipe at the bottom; and if you have water to bother you, you will cut what is called a drain ditch to carry off all the water that accumulates while working. This pipe or box should extend above and below the base of levee. This is the best plan for draining that I have ever found; but the trouble comes in when you wish to use a screen to prevent the fish from passing out. My plan is this: Make a screen of wire, balloon-shaped, as large as a half-bushel, the neck small, so as to fit the pipe in the pond. Use a plug at the outer end of pipe or box, so that you can control the water.

CAPACITY OF POND.

This will depend altogether upon the amount of water passing in and out of the pond, the depth, and the amount of feed given them. Friend R. said he had been informed that 100 five-pound fish would overstock his pond. They would in a few years, but would not themselves. My pond is about 70 feet wide, 140 feet long, and about 7 feet water, when full, and I think it will hold a thousand five-pound fish, and many more. My friends, do not be afraid of overstocking your ponds. If you find you are getting too many, catch them out and eat them.

Andersonville, Ind.

W. S. KALER.

For lack of space we shall have to defer the remainder of this valuable communication until the next issue. While some of the directions given are not quite in harmony with our forthcoming book, of which we have already corrected a part of the proof-sheets, friend K. has some original and valuable hints. The one item of putting clay in the bottom of a pond having a gravelly base, and then feeding hogs on it to get them to stamp it down well, is an exceedingly bright thought. I know from experience that it would do the business to a dot.

HARMONY AMONG BEE-KEEPERS.

An Humble Attempt to Harmonize the Views of Heddon, Cook, and Doolittle, on the Causes of Bee Diarrhœa.

FRIEND BALLANTINE TAKES A SORT OF BIRD'S-EYE VIEW OF MEN, BEES, AND OTHER THINGS.

THE great Dr. Cumming, of London, in his eloquent lectures on the book of Revelation, makes this observation: "A great deal has been written upon this book; much very foolishly, more very rashly; nothing, however, in vain." We reach the same thing in regard to bee literature. Many foolish theories have been promulgated; many rash assertions made, but nothing in vain. All seem necessary to elicit the truth.

The hypotheses and theories formerly entertained in regard to the motions of the heavenly bodies, however preposterous and absurd as they *now* appear to us, were, however, necessary to the evolution of the Copernican, or true solar system, as now received. When these false hypotheses and theories were proposed, they elicited investigation. In proving them false, the true system was by degrees evolved. Astronomers can now calculate with accuracy, and demonstrate with certainty, eclipses, the rising and setting of the sun, for every degree of latitude and longitude on the surface of the globe. They are not even content with this, but extend their knowledge far beyond the limited orbit of the earth, and calculate the eclipses of Jupiter's satellites and Saturn's moons. The data to calculate the velocity of light, the power of attraction, and many other marvelous things, have thus been obtained, in a measure, through foolish theories and false hypotheses.

When we find this true, not only in the science of astronomy, but in all other, may we not expect that the same results will flow from the science and art of bee-keeping? Let us endeavor to demonstrate the correctness of this conclusion.

Mr. James Heddon, of Dowagiac, Michigan, some years ago advanced the new and somewhat startling theory that pollen, the natural food of bees, was the cause of all our "winter's discontent." Some were surprised at its boldness, others were struck with its novelty, while still others were tempted, out of curiosity, to wisely investigate it, and ascertain its truthfulness. These, like the philosopher who, when his companions were warmly discussing, why a bowl full of water would weigh no more with a fish in it than it would without it, calmly suggested they ascertain, first, by weighing the bowl with and without the fish, whether it was so or not, before endeavoring to account for it.

In the conviction of all who have thus investigated the pollen theory of diarrhœa, *per se*, by itself, as the sole cause, it is marked "*Tekel*—weighed in the balance and found wanting." But has there no good resulted from it? Far from this, it has been the means of eliciting some truth. Professor Cook, renowned for his entomological lore and skillful dissection of the insect race, has given a *quasi* indorsement of the so-called pollen theory. He thinks that colonies destitute of this nitrogenous food will winter better than those which have it. When such men are inclined to give the weight of their influence to any suggestion or novel theory, it almost staggers the man of experience, let alone the novice. Taking Heddon's theory, with Professor Cook's experience and judgment in its favor, and

we are inclined almost to say, "There is either some truth in it, or else these men are terribly mistaken."

But, friend Doolittle comes in with his calm, sagacious, and inductive philosophy, and asserts that he thinks the cause of bee diarrhœa is when colonies are breeding, and when the young bees are prevented from having a flight. This view he has sustained by observations, made at various times in his own apiary. We believe there is a moiety of truth in this, although we have never observed the phenomena that friend Doolittle has.

Reasoning from analogy we are brought to this conclusion: That insects, as well as other animals, have their intestines full of a peculiar kind of matter that must be voided shortly after birth, to secure the healthy and vigorous action of the system. This matter is technically known as *meconium*. An infant, a calf, a colt, and even a lamb, will not thrive until this passes off. Is it, then, not a fair inference to say that the young of bees must, in like manner, have an opportunity to void this increment, to insure health and vigor? Let us next try to harmonize this trio of bee-savants.

It is a well-known principle, that bees can not breed without pollen. If, then, there is no pollen in a colony, breeding is out of the question. This being the case, according to friend Doolittle's theory there will be no diarrhœa, because no young bees to suffer.

This will chime in with friend Cook's experience. Colonies winter better with him, that have no pollen, and consequently no breeding. Friend Heddon finds that some of his colonies are dying off with diarrhœa, and discovers that all so affected have pollen; he has not made the observations of friend Doolittle, but infers that pollen is the true cause of the bee mortality. His inference, though wrong in charging the whole evil upon the pollen, which is as innocent of producing the death of his colonies as Vennor's theory of this being a "mild" winter was in producing the reverse, is, nevertheless, to a certain extent, in harmony with Doolittle's theory, which inevitably recognizes the presence of pollen. If truth has thus been elicited, friend Heddon has assisted, friend Cook's experience has corroborated, and friend Doolittle's observations have contributed much to its discovery. These men, then, are not unlike the three princes in the Arabian tale, who were enamored of a fair lady, each being severely wounded with Cupid's arrows. The object of their affection being herself unable to decide the question by making a choice, it was agreed that the three princes should travel for a year in any portion of India, of their own selection, and the one who would secure the greatest benefit for himself and mankind in general would be the happy party. One procured a piece of carpet of so potent a power that it would transport its owner, and others whom he permitted to sit upon it, to any part of the globe desired. Another procured an eye-glass that would enable its owner and others to see any object wished. The third procured an apple, of such divine power as to heal every one, however diseased, that would but smell its perfume. Having all three met at the expiration of the time, at the place agreed upon, each confident of being the victor, one happened to look in the glass, and saw the object of his affection in the agony of death. This being announced to the other two, the possessor of the wonderful apple exclaimed, "If I were only there, I could cure her in a moment." The owner

of the magic cloth said, "All right; let us three just sit down on this cloth, and we shall be there instantly." They did so, and by the application of the apple, the object of their love was immediately restored. But the question, who the happy one should be, was just as undecided as ever. The one with the glass claimed if it had not been for it they would have remained ignorant of the sickness of the princess; the one with the cloth asserted that it was instrumental in bringing them to her assistance, while the one with the apple of marvelous virtue, claimed that the other things were good; but if it had not been for his apple, the princess would have died in their presence.

So Heddon, Cook, and Doolittle are all entitled to some credit, if we have at last found the truth on this subject; but if we have not discovered it, there is progress made. Let friend Heddon proclaim any and every bold and novel view that his fertile and imaginative mind can suggest. It will be tested in the crucibles of hundreds of philosophical minds, and purged from its dross. If it contains the millionth part of a grain of truth, it will be eliminated and carefully added to the already accumulated and fast accumulating treasury of bee-science. If it does not contain a single atom of truth, it must and will be rejected.

WM. BALLANTINE.

Sago, Ohio, Feb., 1885.

Friend B., I like your reasoning, and I pretty nearly agree with you, only it seems to me the basis of some of your calculations ought to be modified a little. For instance, pollen as the cause of dysentery was suggested and discussed at considerable length through the *A. B. J.* over ten years ago. Again, bees are often hatched out in great numbers in colonies wintered in the cellar, and live without any pollen at all until they are a month or six weeks old, and the colonies come out strong and healthy.

PYRACANTHA AS A HEDGE-PLANT TO PUT AROUND OUR APIARIES.

FRIEND OLDROYD'S EXPERIENCE WITH THE ABOVE
FLOWERING EVERGREEN.

IN reading the article from the pen of your friend J. J. Lawson, in reference to pyracantha as a hedge-plant, if it is what I suppose it to be, I hope no one of your many friends living north of Mason's and Dixon's line will be induced to invest any money in it, as I did some eight years ago. Seeing an advertisement in A. M. Purdy's "Small-Fruit Recorder," speaking of it as an evergreen, with beautiful white flowers in the spring, and full of red berries in the fall and winter, I invested five dollars for enough plants to make a hedge about 200 feet long on the east and south sides of my lot. All failed but one plant which I keep as a "remembrancer." It is about 18 inches high, with a few straggling branches, and it has never borne a flower or berry; and as to its being an evergreen, I inclose a slip of the best I could find. Years before that, I had often noticed in the front yard of one of the residences on Broad Street, with a southern exposure, a small scrubby hedge, perhaps 40 feet long, and I wondered why the owner should let such an ungainly-looking row of dwarf bushes occupy a space in his front yard. After mine developed somewhat,

I found they were brothers. The hedge in question is not two feet high, if my eyes do not deceive me. I should surely be very much delighted to have a hedge as described in the "Fruit Recorder" and in GLEANINGS, but there is nothing to be desired in the hedge in this climate.

WM. OLDROYD.

Columbus, O., Feb. 16, 1885.

Thank you, friend O., for your timely caution; but perhaps some in other localities may have had a different experience. If so, will they please inform us?

A WORD ABOUT PATENTS.

"MORAL" AND "IMMORAL."

ED. GLEANINGS:—I notice lately that a good deal is said by friend Heddon and others about the sacredness of a man's right to control the manufacture and use of any article he may have invented, and on which he has got or may get a patent, and all seem to agree that such is according to truth and justice, and that there is but one side to this question; but before I can agree to this proposition it must be made out by better reasons than I have yet seen.

But some will say, "Is not a man's invention his own property? has he not lain awake nights to work it out, etc.?" and I reply there is not nearly so much original invention by any one man as is often supposed. The fact is, inventions grow, and necessity is the mother of them. The research and investigation of the former ages are our stock in trade, so to speak, and we start to build where they left off, and a large part of the patented claims are, when thoroughly sifted, only what some one else used long ago, but never thought of getting a patent.

I have quoted, that "necessity is the mother of invention," and it is interesting to note the way they are brought about. Let there be a demand for an object or an article, such as getting the large proportion of the early honey in the surplus sections, and we have Doolittle and Heddon and Hutchinson and Root and a thousand others lying awake nights, and working out the problem, and presently we shall have a dozen or more inventions with patents, either legal or moral, a large part of which are alike, or nearly so, and quite likely will prove to be what some one else has used years ago; and if not, if some one really strikes something new and valuable, what moral right has he to forbid for seventeen years everybody else from inventing and using the same thing, for it is well known that most valuable inventions are made by different persons, and often at about the same time, although neither knows that any one else was working at it.

I submit, that it is not right to give a man a monopoly of a valuable invention for 17 years, when it is likely a hundred others would work out the same thing without any help from the one who has the legal patent.

L. BECKWITH.

Berlin, Wis., Feb. 10, 1885.

Friend B., it is a fact that very few inventions belong exclusively to any single individual. Almost every thing that comes up can be traced back through different hands innumerable, and frequently it transpires that the one who calls himself an inventor has done, oftentimes, little more than to

couple together and perfect the things that have been worked out by others, a little at a time, here and there. Where so many hands are working on something there begins to be a demand for, the ground becomes worked over and over. The same has proven true on extractors, feeders, cases for holding sections, making sections of one and four pieces, fastening into frames, and, of late, reversing devices for frames. Notwithstanding the above, there seems to be occasionally something worked out almost entirely by a single individual, where he devotes much time to it. Of course, he has, however, to commence on a basis where somebody else left off. Then the question comes. How much right has anybody to a monopoly of these plans and ideas? The grand point that you make, that it takes us all together to bring out any good thing, harmonizes nicely, as you will observe, with my remark at the bee-keepers' congress at New Orleans, under the department of Our Neighbors.

BEE-KEEPERS' CONGRESS AT NEW ORLEANS.

NOTES BY THE WAY.—IN THE NIGHT.

Continued from Last Number.

WHAT a blessing is the modern sleeping-car! A little before midnight I glanced out at the Kentucky landscape. The snow was gone, and bare fields and dry sidewalks met my eye. An hour later the head-lights of the locomotive showed the air filled with large fleecy snowflakes. An event occurred right here that has a great moral lesson in it, and I think it bears especially on us bee-keepers. When railroads were first started, our friends in the South, after more or less consideration, decided on the width of track, 5 ft.; and our friends at the North, without thinking, when they started to lay track, adopted 4 ft. 8½ inches as the width. Simple thing, isn't it? Very likely these early fathers in railroad-ing thought but little about it until traffic demanded that these north and south roads should connect. Even then nothing serious resulted, for a simple transfer of passengers "fixed" it—that is, passengers gathered up their luggage and walked over into a car on the other gauge track. A little later, sleeping-cars came into being, and just now in our journey the change would have to be at 1 o'clock at night. I imagine the passengers scrambling out of the berths of a filled sleeping-car, and piling into another on an adjoining track. Whew! wouldn't there be a fracas? Do you know what they do? Why, they have gone to the expense of a great structure that lifts the sleepers almost noiselessly from the trucks, suspending them in mid air. The trucks are then run out, and others suited for a different gauge are put in their place. After this the cars with their precious freight of sleeping passengers are let down as quietly as they were taken up. This is done so skillfully and noiselessly you would sleep on without interruption unless some one told you of what

was transpiring. The operation of raising up and letting down did not take over two minutes.

"Why in the world do they not tear up these odd-gauged tracks, and make all of the standard size?" said I to Mr. Holmes.

"Why, my dear sir, do you suppose changing the tracks would be all the expense required? All the great rolling-stock must be made over and changed, to say nothing of throwing away good locomotives that cost \$20,000 apiece, or such a matter."

"Well, what are you going to do?"

"Why, we are going to use our present stock until we wear it out, and get along the best we can, changing passengers and changing freight; but all the new work made now is being made with the change you speak of in view. Some time we expect to be able to send any car from Canada to the Gulf of Mexico, and on any road."

The above may not be exactly as Mr. Holmes stated it, but it is in substance. Now, then, friends, do you see its application to bee culture? A great many of us have started just as thoughtlessly as did the railroad men. My neighbor Rice, of Seville, O., when he started with movable frames, just sawed off some sticks and never measured them at all. He refused to listen to my remonstrances, but kept on with his frame unlike any thing anybody ever used before, and until I began to buy bees of him every summer in \$500 lots at a time, each colony having to be transferred before I could make use of it. Arguing in words didn't convince him; but the trouble of transferring each colony into frames like the rest of us use, did the business. He now has no more of those "mongrel" frames.

10 o'clock A. M.—We are just out of Nashville. All traces of ice and snow have finally disappeared; but I have looked in vain for some signs of early gardening; not a trace even, around the suburbs of the city of Nashville, while acres of hotbeds are to be seen close to Cincinnati, where they still have almost zero temperature to battle with.

A sad, sad sight was presented us just before reaching Nashville. Little tombstones, almost without number, covering acres of ground, showed where our boys fought, bled, and died. Can any one look on that burial-ground without almost overwhelming sadness? May God help us, that we may all so live that such an event can never, never happen again.

11 A. M.—Through Southern Tennessee many localities would be difficult for farming and gardening purposes, because one would have to draw dirt to cover the rocks that crop out almost everywhere. The soil is a reddish yellow, but looks very light and fine for tillage.

A good deal has been said, and I think unnecessarily, at least some of it, about the expense of meals on the trip. Now, one can practice economy, and that, too, without the annoyance of carrying a lunch, which many, myself included, so much dislike. At the restaurant on the sleeping-car you can get a good lot of bread and butter for a

dime—good, too, both of them, and many other things in proportion. Very nice oysters are only 25 cts. a dish, and you have a nice little table to eat on. After your repast is over, this little table is just the thing for taking notes, as Ernest is demonstrating, while we glide along smoothly at 40 miles per hour. I enjoy it, any way. If all the roads are as well managed as the Louisville & Nashville, I don't see why anybody should complain.

We do not see horses and wagons at the hitching-posts at the stations we pass. We see rows of horses; but in place of the wagons, only saddles. The roads are so rocky and hilly is one reason, I presume.

12 o'clock.—It troubles me to see so many men standing about in the stores—in fact, all along the way, with their hands in their pockets. It has been a rainy morning, I know; but even during a rainy day, ought our American people to be wasting precious hours of broad daylight with their hands in their pockets? I am afraid there are many thousands throughout our land in this same attitude; but I feel very sure they are not happy in so doing. Don't give away to such weaknesses, boys; do something, if it is a rainy day. Improve your homes, improve your minds, and give a lift in raising humanity by raising yourself.

For some little time back I have been wondering why farmers have allowed a peculiar weed to grow to such an extent; and now it dawns upon my understanding that it is the dried and blackened stalks and pods of the cotton-plant. So we are really gazing on cotton-fields for the first time. The cotton-presses are equally a curiosity, and I had been wondering for some time why there were so many funny-looking "cider-mills."

1 P. M.—As we strike Alabama the rocks disappear, and with them the hills. The landscape seems to be a sort of swamp of evergreens. Now and then are expanses of water around the tree-trunks.

4 o'clock P. M.—A mountain stream comes dashing down among the rocks, which now seem to be more wild and suggestive than at any time before on our trip. In order to reach the high land, the track as it starts up from the swamps endeavors to follow the mountain stream, so to speak. Now dashing, the stream winds a hundred different ways as it plunges through the ravines. As the locomotive can not well do this it crosses and recrosses, taking cuts through hills and across ravines in a way that makes its ascent most exhilarating and bewildering. From the way the engine puffs and labors over about 8 miles of track, it would seem we must have ascended quite a height, leaving the fogs of the valley below. Beautiful little pines and other evergreens, with the fresh mountain air, make it a scene wonderfully fascinating.

Yesterday I felt a longing to see babbling brooks. To-day the longing has been satisfied, if it ever was in my life. Brooks are everywhere pouring down the hillsides from cliff to cliff, rushing and spattering the sides of the track, whether we are on the mountain or in the valley. This is pretty well

down in the State of Alabama. Rushing torrents are everywhere.

Just here the train stopped a few minutes, and we jumped off to witness better the grandeur of this mountain scenery. A boy with a pitcher was singing out, "Here is your nice red sulphur-spring water, only nickel a glass." We handed him a nickel, and were quite willing to take his word that it was the "genuine simon pure," even if we didn't take more than a small swallow apiece. This is near Blount Springs, a famous watering-place.

In the night.—I happened to wake up as the train stopped, and I heard the tree-toads. Before it was quite daylight we were in the turpentine woods. After leaving Montgomery we saw gardens with peas in blossom, and other vegetables correspondingly far along. Canebrakes just now are an interesting sight. It is the same thing the boys use for fish-poles, and the smaller ones were formerly used for reed pipe-stems. On the low grounds the trees are beautifully draped with Spanish moss, which waves gracefully under the influence of the light breeze. Miles upon miles of Alabama is wild land, apparently of no use to any one. The low lands that produce such luxuriance of canebrake and tall grasses, it seems to me might give wonderful crops of almost every thing, if reclaimed from the water seen everywhere.

The soil through all the South has a queer reddish cast. In some parts of Alabama it is a bright brick red, and in others a brilliant yellow. The babbling brooks that follow almost everywhere beside the track and across the country, partake largely of the color of the soil. One of these said brooks I was so enthusiastic over, washed out a part of the track last night, and throws us into New Orleans half a day late.

As we approach the suburbs of any great city, we as a rule expect to see a gradual improvement in the surroundings, residences, farming lands, gardens, etc.; but the suburbs to New Orleans, however, seem to be an exception. The watery wastes give place to a sort of swamp, composed of bushes and small trees. Little canals run out from the railroad track into these bushes, which puzzled me for a while until I saw negroes pushing large flat-bottomed boats along these canals. The boats were filled with wood. Firewood has got to be so high in price that they split off the sides of stumps, cut up bushes, and pick up every thing for fuel. With the mild balmy air, and the grass starting everywhere, I expected to see beautiful market gardens; but if there were any, they were not along the railroad. In the street-cars running out to the Exposition, I saw cabbages and some other vegetables. Most of the gardening seems to be done by hand. Horses and cultivators were nowhere visible; and as a whole, the gardens in no way compared with those in the suburbs of our Northern cities. The soil is rich and light, but the workmen, so far as I observed, did every thing with a spade—digging up the ground, cultivating, getting out weeds, etc., all with the one tool.

To be continued.

He that is faithful in that which is least, is faithful also in much.—LUKE 16: 10.

MYSELF AND MY NEIGHBORS.

Where no counsel is, the people fall: but in the multitude of counselors there is safety.—PROVERBS 11: 14.

MY neighborly talk to-day will be a repetition, as near as I can conveniently make it of a little talk I gave the bee-friends in New Orleans. I may explain, that it was given without any thought of publication. After I got through, several requested I should put it in print. Well, while I shall do so I shall take the liberty of leaving out a good deal that I do not think will be particularly needed here, and I shall also put in some things that I intended to mention, but omitted. The subject assigned me was—

THE PROGRESS OF BEE CULTURE SINCE 1860.

Before starting out with my little talk, my dear friends, I want to tell you how much pleasure it gives me to meet face to face so many bee-friends from the South, whom I have known for years through correspondence. It also affords me great pleasure to notice among them many friends also from the far North, some of them even from Canada, and one or two from Maine, to say nothing of those scattered here and there almost all over the face of our great nation. I do not know exactly why this topic has been assigned to me, unless it is that I am one among the pioneers, as it were, who first started the development of our favorite industry.

Before speaking of the inventions that have come up here and there through the

years that have gone by, I want to say that it seems to me honor and credit is due not only to the one who brings forth an important invention, but to the age in which he lives. When the age is ripe for invention, the invention comes forth, and it can not well come forth until the age is ripe for it; and when this ripeness comes, usually several come out with the same invention, or facts, almost simultaneously. Our good old fathers Langstroth and Quinby, each one of them wrote a book on bee culture; and when each set about his work he hardly knew of the existence of the other. It is greatly to their credit, also, that when these books came to light it was found that they agreed substantially in all important points. When the age was ripe for steam, steam-engines came, and many efforts contributed to bringing forward and perfecting the invention. When the age was ripe for some more rapid means of communication than our mails, electricity came to our aid, and later the electric lights which now illumine these beautiful grounds every evening. The honor of these inventions is not due to any one man. It is the work of the people; and, dear friends, the progress that has been made in bee culture since 1860 is due to a great many different people—the world at large—because there was a demand for the things brought forth, before they ever saw the light of day.

In the A B C book I have told you how I commenced chasing a swarm of bees. I have told you, also, how greedily I devoured all the bee-books that could be then found on the subject. In 1861, friend Wagner

started the *American Bee Journal*; but after publishing a very pretty little sheet at the modest price of one dollar a year, he was compelled to give it up for lack of patronage. The age was not ripe for it. There it stood for four or five years, until I waked up to the subject of bees and honey, as I have told you.

As soon as I learned that a bee-journal had been once published, I did not rest until I had all the back numbers. None but one who has passed through such an experience can imagine with what keen enjoyment I devoured every page of those first twelve numbers. When I get down the old books and look them over now, it thrills my heart anew to remember those good old times that I had with them that summer studying Langstroth and these twelve numbers while I worked with my bees, and verified, step by step, every thing laid down in the books. I urged friend Wagner to recommence its publication. He feared it would not pay, as he had already sunk money in the enterprise. I told him I would write for the journal, and help to make it pay. Of course, I knew nothing of bees, comparatively; but I presume it is only human nature to be *all the more* ready to write for the journals. I do not mean by this that it is wrong for these young enthusiasts to feel like writing. I *did* write, as some of you may remember, and my awkwardness and my blunders not only provoked smiles from some of the veterans, but it stirred them up to come to my rescue; and as fast as I got wrong they straightened me up, as our veterans ought to do. Of course, I was soon in correspondence with Mr. Langstroth; and although it was late in the fall, I told him I wanted the best Italian queen he owned or could get for me. I was a little astonished when I found the price was \$20.00; but I thought if queens were worth \$20.00 to anybody they certainly ought to be worth that to me, for I was going to be a *big* bee-man, and much depends on starting *right* (you know).

The queen came by express, and at the same time somebody made me a present of a dog. The express agent delivered both, saying he didn't know whether the "animal" he led by the strap was the \$20.00 queen, or whether it was in the box. The neighbors laughed a good deal at my investment of \$20.00 in one single "bug." I introduced her to a colony I had been experimenting with through the fall; and when the yellow bees began hatching out, wasn't I happy? Right here I want to emphasize the fact, that had it not been for kind friends who had more mature sense than I was possessed of in those days of my early enthusiasm, I should have been shipwrecked in my bee-ventures over and over again.

Some time in early winter, a sound practical old farmer a few miles out in the country came and inquired about my Italian bees. He was a thorough and successful bee-keeper, and had the Langstroth hives. I with great pleasure showed him my choice Italians, while I talked volubly about bees and new races. He admired the little yellow chaps some, but did not say a great deal.

After I got through talking he very quietly asked me if I supposed my queen would live through the winter as I had got her fixed.

"To be sure," said I, "why not?"

"Mr. Root," said he, "I believe you have the first Italian queen ever brought into Medina County; and for the credit of the county I am a little anxious she should go through the winter. But if you keep her in that little handful of bees, I would not give *that* for her," snapping his fingers as he concluded the sentence.

He finally invited me to come over to his house, and he said he would show me what a colony of bees is like, that might be expected to winter over. To tell the truth, I had never seen a *full* colony of bees, and did not know how many it took; but by his advice my queen was introduced to a good strong colony, and came through all right. Some time toward spring I found a long yellow bee at the entrance of the hive, and, in great trouble, I pushed her into a quill and mailed it to friend Langstroth, telling him my queen was dead. Can you imagine how I rejoiced when he wrote back that the bee I sent was no queen at all, but simply a worker whose body was much distended and elongated by dysentery? My bees wintered pretty fairly, thanks to the friend mentioned above; and by purchase I was enabled to start out in the spring with perhaps half a dozen colonies. I increased to about twenty; got but very little honey, and lost three-fourths or more of them during the coming winter. Never mind. I was learning valuable lessons. The next season I did better, and went to work and made perhaps the first all-metal honey-extractor. Some of the readers of the old *A. B. J.* will remember my ups and downs. At one time I was very much tempted to give the whole business up in disgust. I did for a while decide to do so. Perhaps the laughs and sneers of some of those who kept saying, "I told you so," was the means of stirring me up to prove to them that I was not so much of a crazy fool after all. I went to work carefully and quietly, with the eleven weak colonies remaining after the disastrous winter, and built them up to 48 good colonies in the fall, letting my extractor stand idle for one season. The 48 were all wintered, thanks to the lessons of sad experience. From the 48 I obtained 6162 lbs. of honey, and sold the whole crop at a pretty good price. After that I did not have any more notions of giving up bee culture.

The times were now ripe for a general advance in bee culture all along the line. Mr. Harbison was doing big things in California; Doolittle was making a start in York State; friend Viallon and our worthy president, Dr. Brown, besides many others I might mention here, were doing their part in the South. Our stalwart friend Mr. Muth commenced to buy honey, and put it up in bottles in Cincinnati, and he stands to-day, perhaps, the largest dealer in liquid honey in the world. Had it not been for Mr. Muth's industry and energy in putting honey upon the market, perhaps many of us might be in the background instead of where we are now. D. A. Jones had secured such a wonderful crop in

Canada that a great many of us began to think it was a great big yarn. He was too busy taking care of his crop to write letters or answer questions very much; and all we could tell about it was the stunning statements that had got into the newspapers. Friend Jones kept still, however, and left us to find out as best we could what wonderful things our sturdy brothers in Canada could do when they got well worked up. Just here we began to wonder whether there were any better races of bees anywhere in the world than we had already. The Italians were a great advance over our common bees: what might others be? Frank Benton, from the Agricultural College, in Michigan, put his skill as a linguist with friend Jones's capital, and they two went on an exploring expedition to the Old World. Although some of us do not think the new races they sent home were any great improvement over the Italians, yet I think, dear friends, our thanks are due them nevertheless. They opened up bee culture; the new races demonstrated many new and wonderful facts, and gave us quite an advanced step in the way of queen-rearing.

Within the past year our friend Frank Benton has so thoroughly experimented on just what is needed for sending by mail, and has succeeded in bringing it to such perfection, that queens are now sent across the ocean in the mail-bags with comparatively few losses.

Again, the age became ripe for some improvement in the combs we began to handle so much; and different intellects throughout the land began thinking of combs made by machinery, more accurate than the bees could make them, and all worker combs instead of drone. Investigation showed that the Germans had been using something of the kind for twenty years or more; and, indeed, our friend Samuel Wagner had at one time made comb foundation, but let it drop, as he did the first numbers of the *A. B. J.*, for the good reason that the times were not yet ripe for it. When the time came, however, it sprang up with new vigor in different places. Our friend John Long, whom many of you may remember, and who, I regret to say, thought an assumed name to be better than his real one, began to send out little sheets of wax, impressed with cells. It was a success. I wrote to him to know how he made them, and he said they were made by a pair of plates, and that was why he could not furnish me sheets large enough to fill the Langstroth frame. I at once declared the article should be made by embossed rollers. Although this statement was given in print several months before my first pair of rolls were finished, nobody replied that rolls had been already in use. You know the result when I announced that it was a success. The rolls were honestly my invention, or at least they were made under my direction; but I have since been told that a poor German by the name of Weiss had a pair of rolls, and that the samples sent out by John Long were made on these. John Long said afterward that he told me they were made on plates, to keep the discovery a secret. Friend Newman in-

forms us that Mr. Weiss died in the poor-house.

About this time the queen-trade opened. The bee-keepers were so careless or so heedless that the P. M. G. ruled bees out of the mails. For some time the progress of our industry was seriously retarded by this ruling; for in consequence of it the express charges on a queen worth a dollar and a half were sometimes as high as two dollars and a half. For a while all efforts to get a reversal of this decision proved unavailing; but the times were ripe, and the wants of the nation demanded that queen-bees be permitted to go through the mails. The matter was taken up at a convention in Chicago, if I am correct, through the influence of the editor of the *A. B. J.* and Prof. Cook, including several other friends. To our great relief, our petition was granted. Prof. Cook made a visit to Washington to secure the desired end, if I am correctly informed.

Once more something more substantial for combs began to be called for. Wiring was tried, and a great many said it would not work. Finally Dr. Carlin, then living near friend Viallon, wrote me that fine tinned wire, about No. 30, would support the combs so they were comparatively secure from breakage, and yet they did not in any way interfere with brood-rearing. I found this to be correct by experiment, and now we sell tinned wire for this purpose in such enormous quantities that we purchased over a ton at one time last season. Dr. Carlin, I am sorry to say, was recently killed in an encounter with some ruffians in the far West.

The ripeness of the times just now seems to demand a reversible frame, and many busy brains are working the ground over and over. One sad part of it is, that a goodly portion of them are wasting time and talents in working *over again* the ground that has already been gone over; I mean the class who refuse to take a bee-journal, or who are not conversant with the contents of our back volumes. My friends, before you undertake to make inventions in bee culture—at least before you try to do very much in that line, get the old volumes of our bee-journals, and run them through to see if the subjects have not been thoroughly discussed and well gone over. See, also, the devices that have been pictured out, and may be afterward dropped.

We have now half a dozen or more journals devoted to bee culture. The *A. B. J.* has been for several years a weekly, and is ably managed by friend Newman, who is present with us to-day. Although there has been some fault-finding and complaining, and I fear, at times, a little jealousy, I believe when we get at the real truth of the matter we shall find that the world is large enough for us all. There is plenty to do, and plenty of room for all who are keeping pace with the times; for all who are ready to recognize the wants of the times, and bountiful harvests are in store for those who have proved, by years of holding-on, and faithfulness in what God has given them to do, that they are worthy of bountiful harvests.

We have reports of 500 or more pounds of honey from a single colony of bees; and our friend B. F. Carroll, of Texas and horsemint fame, is with us to-day. Whole apiaries of a hundred colonies or more have given an average of as high as 200 lbs. per colony. California has given us some of the finest honey in the world, and she has also produced it in such quantities that it is largely shipped clear across the ocean.

Is it not a fact, dear friends, that the achievements that have been made have been the result of the work of a "multitude of counselors," as in our text? and is it not likely, that, in the future, God's greatest gifts will be sent in reward for the combined efforts of many busy minds and busy hands? And in view of this, ought we not to exercise a brotherly kindness and charity to each other? Our thanks are due to the great Giver of *all* good, rather than to a single individuals.

In conclusion I want to say a word in regard to charity and kindness to each other. I want to encourage a little more that spirit which Paul describes in the three little words, "Thinketh no evil." I have recently gone over hastily the old volumes of the *A. B. J.* I have re-read some of my writings therein, and am very, very sorry, dear friends, that in my criticisms and reviews I was not more gentle. I am sorry I did not exhibit more of the spirit of kindness and charity. I am sorry, too, so many of us get a little spiteful and uncourteous because we have had different opinions on many things. At the present time I believe quite an unusual state of harmony exists between all parties. It is true, there has been some bitterness manifested, and some flings have been thrown out against supply-dealers—a class which I represent. May I be excused for saying a word just here, even though I *am* the proprietor of a bee-journal, and a supply-dealer? Very likely many of the friends prefer to subscribe for a journal published by one not in the supply business. If so, by all means do so. But, should we not accord to others the privilege of doing as they choose? It has for many years been the custom of class journals to deal in supplies for their special industry. Many of you are acquainted with these class journals, and have taken them, so you know how it is. Now, if there are those here who prefer the *A. B. J.* to GLEANINGS, I think I speak truly when I say I can shake hands with them just as freely, and feel just as kindly. Perhaps my peculiar way of conducting a journal is not to your liking. This would be nothing strange at all; and yet, is it not possible that I have my field for work, and in that field I fulfill the end for which God has intended me? Is it not providential that we are unlike in our tastes and dispositions, and in our views? And yet, dear friends, even though we do think differently, and see things differently, and have different tastes, can we not shake hands in spite of all these differences? And as we gather here from the North, South, East, and West, where the balmy air of the beautiful South blows over us, can we not lay aside these differences, and unite in one common feeling of thanksgiving to the great Father above, who

looks down with kindness and love upon us all?

POVERTY.

FRIEND HEDDON PREACHES A SERMON.

MY dear little boys and girls, do you think you are poor? Very likely many of you do, and have been guilty of sorrow and complaint because you were not as rich, and could not have many of the luxuries that you saw given to other little boys and girls. Did you ever notice that these luxuries do not give children any *lasting* happiness? Did you never notice that the children of those who have the necessities of life are rather happier than those who are presented with luxuries? I am now going to tell you a true story of my own experience that will show you what I mean by "poverty," and that *such* poverty renders happiness impossible.

I live in a small "city" of about 2500 people. About seven or eight years ago, just at the outer edge of town, about three-fourths of a mile from here, lived a poor family, of which there were three children—little Willie, about nine years old; little Mary, about seven years old, and a weak, tender little girl; then little Harry, about five years old.

One afternoon, when the snow was very deep and the cold intense, I asked a number of men in a store if they had heard of any of our town poor who were suffering during this severe winter. They all said no; but, one man added he thought that J. P., down by the river, must be pretty needy for the necessities of life. I went home. After supper, my old habit prompted me to take my usual walk; and, not having forgotten the poor family, I resolved to walk this mile and a half, through snow above my knees, and a temperature about zero. I reached the place just about dusk. The father was out by the door chopping some wood from a poor green log. I went on by, and waited till he got through and went in. I wanted to knock at the door and go in. I wanted to *see* the condition of the whole family. I then returned, and did so. The little house was old, poor, and cold. It consisted of one room of fair size, and a small bedroom and pantry off from it. These were the only rooms in the house. They had just one stove, an old cook-stove—no carpet on the floor; only three chairs in the house. The table was set for supper. Now, girls, you know just about how your supper-table looks, just as you are ready to sit down. Well, this one did not look that way. There were, upon the naked boards, just four old plates, and an old case-knife to each plate—just the eight, and nothing more. Both boys were "bare-foot." The little girl, Mary, had on some old shoes and stockings that no doubt had been cast aside by some one, as worn out. When I was offered a chair Mary had to get up, as there were but three chairs in the house. The little boy, Harry, climbed on to his mamma's lap to keep his feet warm. All hovered over the stove. All their clothes were scanty and poor. I could hear Mary and Harry, and once in a while Willie, keep up a continual teasing, but I could not hear what for. I thought they had put off supper because I was there. I saw no signs of any thing cooking or to cook.

I looked into a bedroom at my right, and saw one bed, poorly clothed, and that was where they all slept together. The teasing of the little children kept up, and pretty soon the mother said, "Pa, don't

you suppose the supper is done?" Then Mr. P. opened the door and looked into the oven; and as I sat just back of him, I looked in too. I saw a pie—at least I thought I did. Mr. P. moved it out, and broke off a piece of corn and water cake, and handed it to Mrs. P. to "try," to see if it were done. You know I told you that Harry sat upon his mother's lap. Well, just as she moved the piece toward her mouth, Harry grabbed it and ate it down before it could get time to cool or be tested. This was not polite or mannerly, was it? Do you blame Harry for this conduct, when he was so hungry? I didn't, and his mother did not seem to. Boys and girls, do you know that politeness is the product of comfort and plenty? Do you know that, during great privation, refined people become rude, cruel, and degraded? Did you ever think that, as long as we have poverty and suffering in our bright land, we shall have crime and wrongdoing?

This one little flat corn cake was the entire supper for the whole family of five. Well, I had seen quite enough. After asking many questions regarding their condition, I hurried home. As I entered the house my mother said, "Rev. Mr. Hall was going to preach his famous sermon at the Universalist church to-night; but I guess there will not be enough there to cause him to preach."

"Well," said I, "I am going over there to preach a sermon, and I guess there will be enough there for me."

I went there and found about twenty persons hovering over the register, and talking of adjourning. Nearly all of them were my acquaintances. I said, "Before you adjourn, would you not hear a short sermon from me?"

"Yes," "yes," "yes," said one and another. Then I got up on to a seat, and told them the story of my last two hours' observation. You never saw a more interested or distressed audience.

After the close of my story a committee was formed, and resolutions passed. The next morning I met Rev. Mr. Hall, with his arms full of loaves of bread. Meat, crackers, clothing, bedding, yarn, money, and other things, were begged; and before noon two cutter-loads of goods were taken to the house of that poor family, and it was hard to decide which were happier—those that gave or those that received. All were very happy; and, in fact, is there any other way that a rich man can get so much enjoyment from his wealth as to use it in relieving the distress of the very poor? I think not.

Some time we shall all discover that there is no true happiness for any, as long as one being is miserable. As long as a part are miserable, a part of each one's life will be unhappy. There is that relationship existing between us all. Never think that you can get happiness from an act that makes some one else unhappy. That has been tried millions of times, and always failed. I hope you will think of my story and these children when you are heavy-hearted because you are not better off. I hope that when you do think of them you will look about and see if you can not find any little sufferers in your own neighborhood. If you do, go right about assisting them. All good people will help you, and you will enjoy the labor better than any other in the world. Some one to start the good work is all that is needed.

JAMES HEDDON.

Dowagiac, Mich.

Friend H., there is one point where you make me a little uneasy in your story.

When you told how you found that family, I wanted to hear you say that you carried them some food right off that night, without waiting for next day. It seems to me I should have felt just like running all the way home and back again. And now I will tell you what more I should want to do. After their immediate necessities were supplied, I should want to find out what the father could work at, and give him some work; and possibly the mother, too, might find some sort of work that could be done at home; and I think all parties will feel a great deal better in such cases, if assistance is given in some way that will enable them to help themselves. Carrying a family through the winter by repeated donations of money or food is always apt to educate them into the habit of being *dependent* instead of *self-sustaining*, as every human being ought to be encouraged to be, if it is a possible thing.

AUNT VIC'S TOBACCO-STORY.

A TRUE STORY FROM REAL LIFE.

THE "tobacco question" has been pretty thoroughly discussed in GLEANINGS; but as I have never added my mite in that direction I will do so now, and will write to the little folks this time, and it shall be a "true tobacco story" that I tell you.

Mrs. Lee and her two children were visiting at Mrs. Benedict's, Mrs. Lee's sister, who lived on a farm a few miles out from Rochester, N. Y.; and as the little Lees had never lived on a farm, nor known much of farm life, of course the surroundings were all a novelty; and one thing that they enjoyed best of all was to climb to the top of the stone wall that ran along the orchard, and watch the canal-boats as they passed by on the Erie canal, that ran along the east side of the orchard. The children were never weary of watching the horses as they trod step by step the well-worn path.

One morning when the children woke up it was raining heartily.

"Oh dear me!" said Kitty; "I just think it too bad to have it rain to-day. Annie and I wanted to go and gather chestnuts." And Kitty hopped to the window, with one stocking on.

Mrs. Lee turned from the glass where she stood pinning on her collar, and said, "Kitty, my daughter, never forget who sends to us the rain as well as the sunshine."

Kitty winced; she felt quite ashamed of her mother's reproof.

After breakfast, Kitty and her cousin Annie went up into the wood-shed chamber where Annie had fitted up a playroom. This left Willie alone down in the dining-room; and as he stood at the window flattening his nose against the glass he could see the two hired men, August and Charley, who were thrashing beans out on the big barn floor. Presently Uncle Jake came in, and, lifting Willie up and setting him on his broad shoulders, carried him out to the barn that he might see them use the flail. This was fun for Willie. He watched them use the flail, then scoop up the beans and run them through the fanning-mill. It was warm work for the boys. They had taken off their coats and jackets, and hung them up. Once when they stopped to rest awhile, August went to his jacket and took from one of the

pockets his tobacco-box, saying to Charley, as he handed him the box, that it was the sweetest tobacco he got down to Smith's the other day, he ever tasted. Wouldn't Charley have a chew? Charley shook his head, for he had not yet tasted the sweets of that "delicious weed." Willie turned squarely around, expecting that August would ask him to take some, but August didn't. After taking out a chew he put the box back, and, shouldering a bag of beans, told Charley to take the other and they would carry them to the granary.

"Sweetest tobacco he ever see," Willie thought to himself. "Well, he's real mean, and stingy too, not to offer me a taste, when I's company too."

Willie looked up at the jacket; there, right in plain sight, was the corner of the box sticking out of the pocket. "I can get it easy as nuffin'," suiting the action to the words. He climbed upon the fanning-mill, and, taking the box out, he hastily transferred some of that "sweet" tobacco to his mouth. He jumped down, and, going to the barn door, saw August and Charley coming back. The tobacco made his lips and mouth smart and tingle; he thought he could swallow it, and thus get rid of the delicious swig. He undertook to do so. Oh how his mouth and throat did tingle! So he spit the rest out, and, wiping his mouth with the sleeve of his apron, thought August didn't tell the truth about that tobacco.

When the dinner-horn blew he rode to the house on August's shoulder. August carried him to the dining-room door, and stood him down on his feet. Aunt Lizzie had a fire in the room, and Willie, being somewhat chilly from standing out in the barn so long, drew Annie's little chair close up to the stove, and sat waiting for the girl to dish up dinner. The warm room and the smell of the dinner made him very sick. Aunt Hannah was the first to notice how very pale he was, and asked, "Why, Willie darling, what's the matter?"

Willie's head grew very giddy, and he came near falling, when Uncle Jake sprang up and caught him in his arms and carried him into the sitting-room and laid him on the lounge. Mamma, Aunt Lizzie, Aunt Hannah, all followed after him. Willie commenced vomiting. What an excitement! Mamma flew around for the peppermint; Aunt Lizzie for the camphor-bottle, and Aunt Hannah for hot water. Willie swallowed the peppermint, but it did not make any difference; vomit again, and, oh so sick and pale! Aunt Lizzie mixed camphor and warm water for him, but that didn't do any good. It was evident that Willie was very sick. Mrs. Lee was getting very nervous. She bustled in and out, though nobody knew what she was doing—herself least of all. Uncle Jake stood by, looking very anxious and helpless; then muttering something about "fooling away time" he rushed into the hall, and, seizing his best overcoat instead of his oil cloth, rushed out in the pouring rain to the barn, and in less than a twinkling, Black Prince, his famous trotter, was going at the top of his speed toward Rochester, scattering the geese out from the mud-puddles in the road, and, utterly regardless of the yelping curs that flew out at his heels, soon reached Dr. Arnold's office. When Uncle Jake drove up, the doctor was just preparing to go out for his afternoon calls. Yes, the doctor would go, for there rose up before his vision a long doctor-bill, which he would have the pleasure of presenting to Mr. Benedict.

"Child sick; company, eh?" and a long string of questions that Uncle Jake didn't hear, for he was turning his horse for home, and close behind followed the doctor's horse.

Willie was looking very pale and ghastly as the doctor entered the room, and, going through the usual examination of tongue, pulse, and head, he looked puzzled, and asked Mrs. Lee what Willie had been eating. "Nothing more than his usual food;" but Willie might have enlightened him, if he had tried, but he didn't. The doctor mixed a large powder for Willie, which didn't taste any better than the sweet tobacco, Willie thought. The doctor told Uncle Jake that he thought the child had taken poison.

"Impossible," said Uncle Jake, turning very pale. Willie's mamma did not hear; if she had, she probably would have fainted.

"Clear case," replied the doctor; "but I have given him a powerful emetic, and will wait until it takes effect."

Willie vomited again.

"What's that?" said Aunt Lizzie, as she wiped off some tiny black specks from the pillow-case. Mamma, doctor, Uncle Jake, and Aunt Hannah came to see. They made such a stir that Willie lifted up his head to look too.

"Why, that's nuffin' but sweet tobacco," he said. Then his mamma went to inquiring, and they soon found out all about August's sweet tobacco.

"Clear case this time," said Uncle Jake, laughing heartily, as Willie told his story. Dr. Arnold buttoned up his oil-cloth coat and pulled on his gloves, and went home through the pouring rain, his vision of a long doctor-bill entirely disappearing.

After the emetic took effect it was astonishing to see how fast Willie grew better. He is a young man now, and does not smoke or chew, and says he had all he ever wanted of tobacco in that one chew of "sweet tobacco," and I think it is a great pity that more do not try a good dose in their first attempt—enough to sicken them ever after at the thought of the filthy stuff. AUNT VIC.

Rockton, Ill.

WALTER'S STORY ABOUT THE FRUIT-TREE AGENT AND THE BEE-HIVES.

A 12-YEAR-OLD BOY TELLS US HOW TO MANAGE WHEN A RUNAWAY HORSE GETS LOOSE IN AN APIARY OF 300 COLONIES.

I NEVER tried to get any thing without paying for it; but I should like to have Ten Nights in a Bar-room to read, and I am terribly scant of cash. One year ago last summer there came a fruit agent here from Nashville, to sell pa some fruit-trees, and that fellow didn't have a drop of bee sense. Pa has his apiary inclosed with barbed wire, about two acres inside. That fruit agent drove his buggy up to the big gate, and tied his horse to one of the posts, within ten feet of where the bee-stands were, and he went into the honey-house where pa was uncapping honey, for we were extracting then, and he was admiring every thing, calling pa the biggest bee-man he ever saw. He wanted to sell him some fruit-trees, you know, when one of the black boys who was bringing in honey screamed out, "The bees are stinging that horse," and none of us in the honey-house knew where the horse was; but we looked out, and that horse had broken loose from the post, and was

coming inside with his buggy, and he turned right in among them, knocking the hives over with his buggy-wheels. The bees just covered him, and he did his very best to get under the ground, till he got one of his buggy-wheels hung around a post, and could not go any further, so he lay right down. We happened to have two large Bingham smokers in full tune, and pa got on his bee-hat and gloves, grabbed a smoker, and called for the black boys with the other smoker, and they came to the rescue like heroes. It took a hero to go out there, 300 stands of bees settling with a horse and buggy. I stayed in the honey-house (you bet I did). The fruit agent went out with his hat off, but soon retired from the scene of action, regardless of ceremony. Pa and the black boys covered the horse with smoke, cut him loose from the buggy, got a rope around his neck, but he lay so still they thought he was dead; but as they pulled his head toward the gate, and came down on his back with a stick, he arose running, and went out at the gate and ran a mile through the corn, and lay down. By evening the horse was better, and pa tied the harness, and the man left. He offered to pay pa; but as pa wouldn't have any pay, he made him a present of some strawberries, which he was to send him the next winter. But that was the last we knew of the man or the strawberries either. It took lots of smoke to persuade the bees that they ought to be straightened, and they didn't want any more foolishness, and so they fought like tigers.

WALTER MARTIN, age 12.

Benton, La., Jan. 24, 1885.

Well, Walter, if you never tried to get any thing without paying for it, I do not believe you have this time, for your story is certainly worth any book in that wheelbarrow full. It is really too bad to think what troubles the poor man had when he came to see you, so pleasant and smiling. I am very sorry he got into trouble, but I don't suppose it can do any particular harm if we laugh just a little. The vivid way in which you tell of the transaction would do credit to a veteran story-teller. I hope you will give us some more letters, Walter.

MISSIONS IN INDIA.

A LETTER FROM ONE OF OUR FORMER OFFICE GIRLS.

DEAR JUVENILES:—The last time I wrote you 'twas on the subject of missions, in which I am greatly interested; and as I have listened to-day to Mrs. Alexander, a lady who, with her husband, has been laboring in India since 1865, I am going to tell you something she said about the Hindoos.

The only god they accept, you know, is represented by great wooden idols, built by their own hands; and their belief is, that after death their souls enter the body of some animal, either the cow, oxen, monkey, or snake. Isn't that dreadful? In consequence of this, none of these animals are ever killed, and Mrs. A. says the reptiles are growing so numerous that, in 1883, 20,000 people died from the effect of snake-bites; the monkeys are so plentiful and so mischievous that property is being continually destroyed by them.

One old gentleman met her one day and mourn-

fully told her that they were tearing all the tile from the roof of his house. "Why don't you kill them?" she asked; but he gravely replied that he might be killing his *own brother*. Isn't that funny? You wouldn't stand back for relationship's sake, would you, my little men, if a snake should cross your path? Just think what these missionaries who go out there so gladly to do the Lord's work have to bear, and how patiently they do brave all dangers for his dear sake. They don't mind such little annoyances as lizards scampering over the walls, and dropping, occasionally, on their heads below. In fact, they rather welcome them, as they eat the flies; but the terrible cobra de capello, scorpions, centipedes, are tough citizens to deal with.

Among other troubles they have smallpox all the year round, and nothing is done by the natives to stop its spreading. In their ignorance and superstition they believe that it is some punishment sent on them by their gods for certain misdeeds, so nothing is done for their sick and suffering, except, in occasional circumstances, throwing ashes over them when the dreaded itching begins.

Mrs. Alexander, who speaks and sings their language beautifully, says that, when she enters the huts of some of the villages for Bible-reading (especially where she is not known), it is not strange to be surrounded by fifty women in a few moments. Mother Eve's failing is predominant, even here. They examine herself and apparel closely, and ask numberless questions as to the race she represents.

It is no light work, here, dear little friends, for either man or woman to come boldly out on the Lord's side; for when one accepts the Savior here he has to give up mother, wife, children; in fact, every thing which goes to make life here happy; for when a Brahmin once loses caste, as he does when he espouses Christianity, he is dead as far as his family is concerned. Little girls are betrothed here at four and five, and married when ten and twelve years of age. Mrs. A. told of one little married lady, about 14, who, while home on a visit to her mother, was converted. When she returned to her husband they commenced persecuting her—accused her first of theft; they tested her innocence by holding her feet over the live coals until they were blistered. As she had nothing to confess, even then, they gave that up; and as her husband died shortly afterward, she was accused of poisoning him. In fact, she was persecuted so that she fled to the Christians for refuge. Eventually she married one of them, and is now one of the most efficient workers in the corps.

Mrs. A. closed her discourse about this good work, with an appeal for prayers and what material help could be given. Dear little friends, do you realize how the missionary pennies you give in, Sabbath after Sabbath, help? Let me tell you what we are doing in our Sunday-school. Every child who will pledge himself to a penny a week is given a bank to take home with him, and last Sabbath the banks which were called in, after being out ten weeks, yielded about \$20.00. Doing pretty well, isn't it? The banks were then given out again. I have nine little boys in my S. S. class, and some got quite interested in trying to see if they couldn't have more in their banks, when added up, than their teacher had, and I am not so sure but that they succeeded. Do you like the idea?

Washington, D. C., Feb. 5, 1885.

And so it is true, dear old friend Bess, that

BESS.

you have actually become a teacher in the Sunday-school, and have nine little boys in your charge. As I read your letter my mind goes back to the mild, demure-looking little girl who came to me years ago, and asked for a place. In due time that meek childish form grew larger and stronger, and Bess became a power in our business, and now she is beginning to be a power in the army of the Lord, unless I am greatly mistaken, and for the same may God be praised.

MORE ABOUT GUNS.

SOMETHING ON THE OTHER SIDE OF THE QUESTION THIS TIME.

I SHOULD like to tell Mrs. Chaddock, that if her "big boy" has had the "bringing up" which we may reasonably suppose she has given him, she will not regret satisfying his desire for a gun. I have no boys, but I was a boy myself not many years ago, and am still fond of a gun. It is a very useful instrument, when properly used, and on a farm it plays an important part in the destruction of skunks, hawks, and "sich like varmints."

A boy who aspires to be a gentleman will be one in the use of his gun; not only in avoiding the wanton destruction of God's innocent creatures for the sake of killing, but in the matter of frightening his nervous mother and sisters. I think girls as well as boys, should be carefully taught how to use a gun; not only for the practical benefit they may derive from it, but for their feelings as well. The nervous apprehension at the presence of a gun will disappear with a practical knowledge of the use and care of firearms. In their use, however, the observance of the following simple rules should be insisted upon:

1. Remember a gun contains elements of danger, and must be handled with a firm hand—not with the tips of the fingers, just ready to drop it.
2. Never point a gun, loaded or otherwise, at any person.
3. Never lean a gun against the wall (unless in a corner) or leave it in any other position where accident may cause its discharge. Have a dry place to hang it, in the house, and keep it there when not in use.
4. In practicing, never place a target on any building, but in open ground, where you can see beyond it, at least as far as the shot are likely to be thrown—say 20 or 30 rods, if you are using a shotgun.
5. Kill only such birds and animals as are unmistakably injurious when alive, or of some use when dead.

A young beginner should take his (or her) first lessons from some careful and at least moderately skillful person.

BURDETT HASSETT.

Howard Center, Iowa, Feb. 24, 1885.

Thank you, friend H. If our boys or girls must have guns, I hope they will observe the rules you give; but I confess I should be better pleased if they did not care for them. Ernest has a gun, and sometimes it seems to be handy; but I do not believe it is called into requisition in our locality more than once in a year. When I read of the accidents that are happening almost contin-

ually with firearms, I can not help concluding that, as a whole, their convenience does not make up for the harm they do; but, of course, I may be mistaken.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows: viz.: *Sheep Off, The Giant Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room.* We have also *Our Homes, Part I.* and *Our Homes, Part II.* Besides the above books, you may have a photograph of our old house apert, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

"A chiel's amang ye takin' notes:
An' faith, he'll prent it."

WHEN in New Orleans we secured lodgings with a widow lady, where we had been directed. As we left early in the morning for the Exposition grounds, and retired late in the evening, we did not get much acquainted with the family. One evening, however, just as we were getting ready to retire, I got to thinking about Huber, and began to be almost homesick, as I imagined that just about that hour he would be teasing for his papa. All at once a babyish voice, sounding not unlike his, caught my ear, from the next room. I listened, and felt a great longing to get hold of the little one. Ernest, however, declared it would be taking a liberty—that they were strangers, and it was late, and so I went to bed without getting hold of the baby; but his childish prattle pulled at my heart-strings every time he spoke, so I could not go to sleep. It was the same next night, and I began to feel as if I could not stand it much longer, unless I could have that baby in my arms. Next day we were obliged to be in the vicinity in the middle of the day; and as we came into the front yard, there among the violets (you know they are in bloom in New Orleans in March) was a pretty, sweet-looking little girl, and on the steps was the mamma with that "said baby." It was not the lady of whom we engaged the rooms, but a younger woman; and although I was a perfect stranger I stepped over the rules of etiquette, and begged for the baby—and I got him too. He seemed as glad to see me as I was glad to see him, and in a little time he got his soft fingers in my whiskers,

and the other hand a hold of my ear, and then he got his little mouth up against my cheek, and in a regular baby fashion showed his appreciation by trying to put me in his mouth, as if I were something good.

My little friends, that baby was to me like a good big dipper full of cool spring water to a thirsty laborer. Perhaps I looked my inquiry, for pretty soon the mother replied that baby's papa was dead. Poor little "Jules"! Was it possible that his little mind imagined that it was his real papa who hugged and kissed him, and talked to him? The little girl came up; and as I shook hands with her, and talked with her, her mamma told her to tell us where papa was. A sober look came over her pretty childish face, and she raised one little hand above her head as she replied, "Papa gone way up, heaven." In an instant a picture came before me of little Huber pining for his papa, who could never come back in *this* world. It would be no harder for him than for thousands of other little ones who have to go through life without a father's love.

Now, my little friends, if your papa is where you can see him and love him every day, will you not remember to thank God for it, and remember poor little Jules; who has a mamma to love, it is true, but can never see his papa, even though he grows to be ever so old?

A TEACHER WHO TREATS.

I take the opportunity of writing you a letter. We sold 75 lbs. of honey this year. We have three hives. Honey is 15 cents a pound here. It is very cold to-day. I go to school. The teacher gave us two weeks' holidays. He is going to treat his pupils the last day.

EDDIE ORRELL.

Vernon, Ind., Feb. 8, 1885.

25 LBS. PER COLONY FOR WINTERING.

Pa has 17 colonies of bees. One hive of bees swarmed twice, and he separated them each time. We did not have as much honey last year as we did the year before. We always winter them on their summer stands. We pack them in chaff, and they live through the winter. They eat about 25 lbs. of honey through the winter. F. C. BENNETT, age 11.

Acushnet, Mass., Feb. 9, 1885.

COUNTERFEITING COMB HONEY.

My father has 24 swarms of bees. My uncle, Stephen Rifenberg, has 40, and makes lots of honey. We have had some very cold weather, 37° below zero, and deep snow. Can any one make counterfeit comb, and fill it with honey so that it can't be detected from genuine honey?

JOSEPH H. SNYDER.

Corey, Mich., Feb. 28, 1885.

No, Joseph, nobody can make comb honey, and it is a shameful piece of falsehood for the newspapers to take it up and keep passing it along as they do.

TENEXINE.

Did you know that tenexine was good to mend dishes with? Ma says that it is the best thing to mend them with she ever had. Pa's bees have been confined for quite a long time without having a flight. I wish it would be warm a few days, so they could come out. I helped my sister gather Osage-orange leaves for the silkworms. We got awful

tired of it. They ate whole heaps of them. Ma had to make us go sometimes. We attend to them in partnership.

HERBERT DYKE.

Pomeroy, Ohio, Feb. 2, 1885.

AN 8-YEAR-OLD PARTNER.

My Uncle George has 60 colonies of bees. He calls me his partner, and I help him take off honey. The bees had a nice fly last Friday, and uncle says they are in fine shape. My pa is helping him build 100 chaff hives for a man in Ohio.

GEO. D. HILTON, age 8.

Fremont, Mich., March 2, 1885.

Well, George, that is pretty good, if you have got an order for 100 chaff bee-hives from a man who lives in Ohio. I admire your energy and zeal. I hope Uncle George will prosper. I suppose when you hang out your shingle it will read, "Uncle George & Co.," and of course you will be the "company."

CLAUD AND HIS MOTHER.

I am a little boy 11 years old. My ma keeps bees; she has two stands. She had 4 stands last fall. She has two Langstroth hives; two swarms died. Ma said they starved to death. They were in the old box hives. I have a Texas pony. I ride it. I go to school. My pa has 6 horses. We have some lambs that look like rabbits, all but the tail. This winter I embraced religion. I joined the Baptist Church.

CLAUD H. SMITH.

Boonville, Ind., Feb. 23, 1885.

So, Claud, you are a member of the Baptist Church, are you, even though you are but eleven years old. Now, my young friend, whatever you do, or whatever you forget, do not forget you are a church-member. Keep the thought constantly before you, and let the world know that you realize what it is to have stood up before men and profess to be a follower of the Savior.

A LOST PENCIL.

The other day Buddie brought some hay from the store to feed our old cow Lily; and as we were giving it to her my little sister Effie spied this pencil. On inquiry the hay was out of a barrel that my pa received from you, in which were packed smokers, a comb-bucket, and other tinware, and we supposed whoever put the things in the barrel lost his pencil, so here it is all the way back from Texas. My pa has 34 stands of bees; sister Alice one, and Buddie one. They commenced bringing in pollen on the 1st of February (on Sunday); was that wrong?

LIZZIE L. MULLIN, age 9.

Oakland, Texas, Feb. 25, 1885.

Many thanks, Lizzie; and although none of our clerks can remember of having lost such a pencil, we know you mean to be honest. That is right. Even in little things we should make it a point to keep nothing but what is justly our own.—Bees are not rational nor responsible beings, and therefore they can not do wrong, as little girls can; and herein is the difference between humanity and the lower animals. "The Sabbath was made for man," and not for bees.

A SHORT LETTER.

Pa has 2 hives of bees. One bee stung him on the hand when he was smoking them last summer. I like honey very well. I go nearly every day to

school. I read in the Fifth Reader. I have three sisters, younger than myself. LILLY WHITE.

Columbus Grove, Ohio, Feb. 20, 1885.

A GOOD REPORT FROM A YOUNG BEE-KEEPER.

I bought one hive of bees last spring. They swarmed five times. Two went off, but I saved 3. I sold one to my brother, and one to my sister. I got no honey. They are all in box hives, but I intend to try the Langstroth hive next summer.

SELBIE D. GROVE, age 14.

Pewamo, Mich., Feb. 18, 1885.

THE JERSEY HEIFER.

Pa has 65 stands of bees. We live on a farm a mile and a half from Cumberland. We have 48 acres of land. I go to school. I watch the bees in summer, and I get five cents a swarm. I am named after my father. We have a good many strawberries. We have a Jersey heifer.

THOMAS FOOTERS, JR., age 10.

Cumberland, Md., Feb. 3, 1885.

THAT CROSS MAN.

My father has no bees, but I am going to write a letter. I have lots of pigeons, and some cats. There is a man at our house, and he is as cross as a bear. If I go in the barn he will come and drive me out. We have had good skating here all winter, but I have no skates. Little Huber would like to be here to slide on the ice, I think. DANNIE McCORMICK.

Cameron, Pa., Feb. 11, 1885.

So, Dannie, you have a cross man at your house, have you? Well, now, I have noticed that wherever there is a cross man there is almost always something else. Shall I tell you what that something else is? Well, I suspect it is a mischievous boy, and I shouldn't wonder if his name is Dannie McCormick.

A DANGEROUS KIND OF SPARKS.

Pa takes GLEANINGS. I read how Mr. C. F. Atwood set his bees afire with the sparks from his smoker. Pa puts green grass in the top of the smoker, so as not to let the sparks fly out, and by so doing is never bothered with sparks—only around my elder sister. Pa has a draft in the bottom of his smoker. Our bees gathered lots of honey from red raspberries. They are quite numerous here, and make very nice honey. GENEVIEVE HILL, age 10.

Randolph, N. Y., Feb. 8, 1885.

Now, my little friend, suppose your elder sister should happen to get her eye on this letter: wouldn't she just "go for" you?

FROM A YOUNG BOOMHOWER.

I am a little boy 6 years old. My name is Novice Boomhower. I was named after you. My pa keeps bees, and I am going to be a bee-keeper too.

NOVICE BOOMHOWER.

Gallupville, N. Y., Jan. 6, 1885.

Right welcome you are, my young namesake. And so it is indeed true, that since the time I called myself Novice, a boy has grown up and written a letter. We know all about your papa, for we have seen a picture of his apiary.

HARVEY'S AGE, AGAIN.

My papa has 35 stands of bees living; 20 have died. Some had too much bee-bread. Pa thinks that killed them, as some of them left considerable honey.

We got 1500 lbs. of comb honey in one-pound sections last summer.

Harvey Baer, I guess you are 12 years old, but you stated your example wrongly. You should have said, "My age, minus $\frac{1}{2}$ of my age, minus $\frac{1}{4}$ of my age, equals 3." MELLIE McFATRIDGE, age 11.

Deer Creek, Ind., Feb. 3, 1885.

A WET PLACE FOR BEES.

My pa started with two old moth-eaten bee-gums year before last, and now he has got 23 hives from them, and would have had a good many more if the moth had not killed them out so much. It overflows where we live. We live on Red River. My pa has to put his hives up on benches to keep the water from drowning them out. Pa is afraid of bees, and I have to work with them a great deal. We got 500 lbs. of honey last year. JOHNNE DUDNEY, age 14.

Collinsburg, La., Jan. 28, 1885.

ABOUT THE SILKWORMS.

I will tell you about my silkworms. I bought 1000 eggs; about the first of May they hatched, and they looked so little. They were black, but began to change color, until, at the last moult, they were of a light yellow. The Osage orange grew close to our house. Ma said when they were fed they sounded like snow falling, so many of them chewing. It was the nicest time of all to see them spin. They made nice yellow cocoons. I sell eggs.

ETHEL DYKE, age 11.

Pomeroy, Ohio, Feb. 2, 1885.

TACKING BEES IN THE HIVE.

My father has five colonies of bees. He bought them last fall. He put them in the cellar, and tacked wire cloth over the entrance of the hive, to keep the bees from coming out. He does not intend to shut them in the hive next winter, because they crawl down against the wire, and die, and it is a great deal of bother to get them out. Our bees are hybrids, and they are very cross.

ELVIS H. HOLLOWAY, age 13.

Rolling Prairie, Ind., Feb. 7, 1885.

RABBITS AND OPOSSUMS FOR FOOD.

My father takes GLEANINGS, and thinks it is "just splendid." He has six colonies of bees, but they did not make much honey this year. I have two brothers and two sisters. I like to read the young folks' letters very much. I have two birds, Betsey and Chip; and I have a dog named Shep. When the snow is on the ground he and myself go out and hunt rabbits. I like rabbits, don't you? and opossums too. They are just splendid—to eat, I mean.

MABEL C. COTTON, age 11.

Wabaunsee, Kan., Feb. 6, 1885.

HOW THEY CAUGHT THE SWARM.

We have a swarm of bees. The way we got them was this: One day a playmate of mine and myself were playing, when I heard a humming noise, and, looking up, saw a swarm of bees flying over. We beat on old cans, and any thing we could get hold of, and at last they settled on a tree just outside of our yard. Then going into the house I told my mother, and she went out and helped us fix a box for them. Then we put a sheet on the ground, and put the box on the sheet, and then shook the tree, and the bees fell on the sheet, and went into the box, where they have stayed two years without swarming.

ELMORE WILSON.

Allerton, Wayne Co., Ia., Feb. 13, 1885.

THOSE THREE SWARMS—SEE PAGE 852, 1884.

I will try to explain about those three swarms of bees. The first swarm went into the house between the floor and plastering, about 4 o'clock Saturday evening. On the following Monday, about 10 o'clock another swarm came out and went in the same place, and about 3 o'clock in the afternoon of the same day another small swarm went into the same place. This was in the swarming season. My uncle lives in town, and does not keep bees. My brother sends a package of seeds. He wants to know if they are the seeds of any of the family of purple fireweeds.

PERLY CRANSTON, age 13.

Woodstock, O., Jan. 11, 1885.

We can not name the seeds you send, friend Perly, but will plant them in the spring. They are larger than the seeds of the fireweed.

HOW HARRY'S MOTHER INTRODUCES QUEENS.

My mother keeps bees. She gave me a swarm my birthday. They made me about 75 lbs. of honey last season. My mamma does not have to cage queens to introduce them, unless she is in a hurry, for she knows just when they will take a queen. When they have young eggs in the hive they are quite independent, and will not accept a queen unless she is caged. Mamma put one queen into five hives, and did not cage her once, and she also took two black queens from two hives standing near each other, and changed them right off, and the bees did not know the difference. Mamma can't change queens unless they are of the same color. She takes GLEANINGS.

HARRY B. HENDERSON, age 11.

Wayne, Mich., Jan. 11, 1885.

LIZZIE'S REASONS FOR USING DOUBLE-WALLED HIVES.

I go to school. I have one brother who has 7 stands of bees. My grandpa has about 60 hives of bees; he attends the county and State bee-keepers' meetings. He uses brick hives two stories high, with a double wall, having one inch dead-air space between the walls. He uses the L. frame, and has room for ten above and ten below. He says they are warmer in winter and cooler in summer than the other hives.

LYDIA J. DAVIS.

North Salem, Ind., Jan., 1885.

Well, Lydia, you have got hold of a great truth that seems to puzzle many of the veterans; and that is, that a properly made hive, protected by chaff or otherwise, is as efficient in keeping out the great heat in summer as it is the severe frosts of winter.

SHOOTING A DEER, ETC.

My pa had 17 swarms last fall; four of them are dead now; two of them he got from you last summer. There are no other bees near where we live. Pa says the drones can not feed themselves. He says, when the worker-bees do not want them any more they do not feed them; and when the drones are almost dead the bees lead them out and they soon die. Pa got \$20.00 worth of honey from one swarm, in one-pound sections. They were black bees.

Pa and I were up in the woods last summer, and killed a deer. It was a small one. Pa carried the deer and I carried the gun. The mountains are high here, and we get lots of berries.

GEORGE M. WYKOFF, age 10.

Cameron, Pa., Jan. 7, 1885.

THE WAX-PLANT.

I and my little sisters help mother churn, and help father extract honey. Our aunt has a wax-plant which has pretty white flowers. They yield so much honey that, during the night, it drops on the floor. Father has been taking GLEANINGS for seven or eight years, and we like to read the little folks' letters.

NANNIE S. CLEMENTS, age 9.

JANIE'S LETTER.

Father has 49 hives of bees, Italians and hybrids. I should like to see Huber and Blue Eyes, and skate on your carp-pond. We do not often have ice thick enough to skate on. I have a pet cat named Tabby. Father wrote these letters for us, as we were afraid you could not read our writing.

JANIE M. CLEMENTS, age 7.

Dalton, Ga., Feb. 2, 1885.

FEEDING THE BIRDS; BEES ON BURDOCKS, ETC.

Papa has 83 colonies of bees packed in chaff on their summer stands. My sister Lucy and I nailed a good many section boxes last summer, but the bees did not gather any honey, so we did not use them, and papa had to feed the bees three barrels and a half of sugar.

We have six pullets that were hatched the last of June, 1884, and they have already laid nine dozen eggs.

There was a patch of burdocks back of the barn that the bees seemed to be busy working on all the time the weeds were in blossom.

Papa scatters wheat around for the snowbirds, and they come every morning to get something to eat.

ALICE HURBUT.

West Bethany, N. Y., Feb. 21, 1885.

THIEVES IN THE APIARY—GOT 'EM!

Last summer, thieves got in our apiary three times. The first time, six boys came with a wagon and got about 75 lbs. of honey. The next day we fixed a tent so that we could stay out all night. The next night father and I were in the tent when the thief came and began to lift the bee-hive cap, when father heard him and threw a rock. It hit a board in a fence by him, and one of the thieves (there proved to be two), while jumping through the wire fence, caught his coat and tore a piece of it off. We made no effort to find out who these boys were, but in the course of a month or two they came and offered to pay the damage. Father accepted the offer.

LUKE LINDLEY, age 9.

New Providence, Iowa, Jan. 25, 1885.

Well, Luke, it seems to me as if a wire fence were a pretty good thing to have, does it not? That bit of cloth probably did the business. A detective would by the aid of it find the boy pretty surely. It seems to me the boys must be pretty bold in your locality, if they get so that they come six at a time, and with a wagon. I hope it will be a lesson to them.

THE LIGHTNING CALCULATOR.

I go to school, and study reading, writing, spelling, and arithmetic. I can add an example containing six columns of seven figures each, in 24 seconds.

FROGS.

I caught a frog last summer, and I examined his mouth, and found that his tongue, unlike that of other animals, is attached to the fore part of his lower jaw, and extends down his throat. They live on flies and bugs. When they want to catch one they throw their tongue out, and then the fly sticks

to it, and then they draw it back in. All this is done with the rapidity of lightning, apparently.

JEROME COON, age 12.

Hayfield, Crawford Co., Pa., Feb. 5, 1885.

Many thanks, Jerome, for the fact that you give us in natural history. I presume when the frog wants his long tongue out of the way, he just swallows it; is that what you mean? I wonder if Prof. Cook knows this about frogs.

DEATH OF THE IMPORTED QUEEN.

Pa has about 100 hives of bees. He got about 4000 lbs. of honey from 60 hives. He gets 12½ cents for comb and extracted honey, and 18 cents for section honey. The best honey-plant here is the horsemint. About two months ago ma went out into the apiary, and found our imported queen dead. We had been raising queens from her, and pa left off the lid, and the mean robber-bees robbed it. Don't you think they did a mean thing? O. H. BROGDEN, age 10.

Bryan, Texas, Jan. 11, 1885.

It seems to me a little mean to think robbers improve every such opportunity, my young friend; but I guess most of the fault belongs to your father for forgetting to cover the hive. It is pretty sure death to a colony, to forget and leave the cover of the hive off when robbers are troublesome, and your letter is a good reminder.

THE CHRISTMAS-TREE: TOADS, ETC.

My grandpa takes GLEANINGS, and I like to read the letters in it from the young folks. It makes me feel acquainted with the boys and girls who write for it. We are having vacation now. Our school closed just before Christmas. We went to school the last day, and were all very much surprised to find that our teacher had a Christmas tree for us, with presents for every one. It made us boys, who had been troublesome, ashamed, and we are going to try to do better next term. We have got for her a copy of Longfellow's poems, and are going to put it in her desk. We are in hopes that she will be as much surprised the first day of the term as we were the last.

My grandpa's bees have all gone to sleep for the winter. I was reading in GLEANINGS a letter from Charles Leyvraz, about skunks eating bees. Bees have a great many enemies, but I did not know before that skunks are one of them. Our bees are troubled by the toads. They will go up to the hive, and when the bees come out they will stick their sharp tongue out so quickly that the bees do not have time to sting them. Sometimes we could see half a dozen toads by the hives, waiting for the bees to come out. At night, and after a shower, we had to put boxes up beside the hive. A. POWERS.

Woodstock, Vt., Jan. 10, 1885.

PENNING UP RABBITS, ETC.

My pa keeps bees. He has been at the business two years, and he likes it better than any thing he ever undertook. There are a great many bees in this part of the country, but they are kept in old box hives. Pa says he will not have box hives. He has all his bees in Simplicity hives. There is a man in this neighborhood who made some of the funniest little hives you ever saw. They have two stories and a gallery, or portico, in front.

My pa says you went to a heap of trouble setting those boards in the ground around your rabbit-yard. He says you could have just laid the boards

flat on the ground, as near the wall as possible, and it would have answered, as the rabbits would never think of going back to the edge of the board to scratch, but would scratch at the wall. The same will keep rats out, only the boards must be put on the outside of the pen. MATTIE F. DILLEHAY.

Milford, Ellis Co., Texas, Jan. 5, 1885.

Thank you, Mattie. Very likely your plan of fixing the rabbit-pen will do; but boards laid on top of the ground will warp and roll up so as to be unsightly, will they not? I think I should prefer them set in the ground, as ours are.

A NEW BUG-TRAP, ETC.

I can answer one of the questions that were asked in GLEANINGS. Iron was made to swim, see II. Kings 6:6. I found it myself in the Bible. The place was in the river Jordan.

I will tell you of an invention my papa has made, and of which I send you a small paper pattern. He thinks it would save paying money for Paris green. He can clean the vines nearly as fast as he can walk. The mode of catching is to hold it in your left hand by the handle, which is a wire running from each front end to the middle of the back. In the right hand carry a broom, brushing bugs of all kinds into the basket. Then make a bonfire of straw, and throw them in. I think this is something new, and will be a benefit to you, if you raise potatoes. EDA N. WEDGE.

Friendsville, Neb., Feb. 20, 1885.

Friend Eda, your bug-trap, if I understand you correctly, is something to avoid the necessity of stooping over every time you find a bug, and I shouldn't wonder if the idea were a very good one. It seems to me that a long-handled dipper, however, would be just as good, would it not? Take the dipper in one hand, and a light broom or stick in the other. Knock the bug or bugs into the dipper, then go to the next hill, and so on.

BITTER HONEY.

Pa has 5 stands of bees, and ma has 3. Pa was looking at them to-day, and one of his was dead. Ma's are all right. The last honey we took from them last fall was bitter. Some one told us it was the honey-dew, but pa thinks it is honey they gathered from a tall weed that has yellow blossoms. The blossoms are in a cluster on the top of the plant. We do not know the name of it. Last year was our first one with bees.

HOW TO FEED.

The way we fed our bees was this: We put the sugar syrup in pie-pans, and cut a piece of paper the size of pan, and made it full of holes, and laid it over the syrup. We spent about \$30.00 on our bees last year. The first hive we bought we got two swarms by transferring, and 25 lbs. of honey. We had an Italian queen given to us; the others we bought in old-style hives, and transferred them into Simplicity hives. We did not get any increase from them.

CARP-PONDS, MUSK-RATS, ETC.

My grandpa has a carp-pond. He has been troubled by musk-rats this winter, making holes in the dam, and letting the water out. There have been a good many mink-tracks around the pond. They take fish too. I think it more likely the musk-rats instead of the crabs made the holes in your fish-pond.

HOWARD ZIMMERMAN, age 12.

Franklin Square, O., Jan., 1885.

OUR HOMES.

But the wise answered, saying, Not so; lest there be not enough for us and you; but go ye rather to them that sell, and buy for yourselves.—MATT. 25:9.

THE twenty-fifth chapter of Matthew as a whole, seems to be concerning providence; that is, it tells of the awful consequences of going through the world in a heedless, slipshod, careless way. It tells what will be the end of those who make no provision for the future; and the text I have selected touches especially on those who expect to borrow of their neighbors, to make up for the consequences of their foolish forgetfulness. At first thought one might think the verse sounded a little hard. The parable speaks of two classes of people, and in this case there was an equal number of the foolish virgins and the wise ones. I am afraid it is as bad as that in our day, dear friends. There seem to be about as many people who expect to get through the world burdening their neighbors, as there are those who expect to bravely shoulder the responsibilities of life. Forgetfulness does not seem to be quite the word to apply to the five foolish virgins. Our Lord calls them foolish. They were foolish, because they made no provision for something they *knew* they would want and must have. The tramp who stops at our doors, and asks if we can not give him his dinner, is a glaring type of this kind of foolishness. There is no forgetfulness about it. He voluntarily and deliberately decides to depend upon somebody else to buy his food; and more than that, he does not even propose to do the cooking, to say nothing of setting the table, washing dishes, and putting things away. I should call it worse than folly. We can not call it stealing, because he boldly looks us in the face, and proposes that we give something for nothing. On page 179 of our last number, Prof. Cook makes the following statement: "Something for nothing is the bane of our age." Jesus intended these words to have their application in a spiritual sense, no doubt; but I think he intended it also to apply to temporal duties. One who makes provision for the needs and the demands of this world, who strives not to be a burden upon any one, and to accord to every one his just rights, as a rule makes provision for the world to come.

It has sometimes seemed to me as if my teachings and exhortations were a good deal the same thing over and over; and I have thought again, that perhaps this is the field God has given me to work in, and that it is my duty to keep going over and over on this same ground, line upon line and precept upon precept. The matter is constantly before me, and I am constantly being saddened because of the number who come to me wanting something to do; and with sadness and sorrow I am obliged to say it, a very great many of those who complain that nobody will give them any thing to do, are like the foolish virgins. If I send them off in the fields to work, in half an hour they will come back, loitering around for a drink of

water, wasting the precious morning hours. When I say to them, "My friend, when you started out for the field, why did you not remember that you would soon be thirsty, and take the jug in the well-room along with you, filled with water?" And so it is all through. They often go to their place of work without their tools, and then come back very leisurely and deliberately for something to work with, or for what they should have known would be needed. I do not want to have you think we have many such with us here now, for I can not keep such long; I am absolutely obliged to let those go who take no thought nor responsibility in regard to the needs of the day. I have often wondered if they would work in the same way if they were working on their own ground; and after watching carefully, and looking into the matter, I am obliged to admit they would. It is not altogether selfishness, then. They wrong themselves as well as the one who should undertake to employ them.

Now, then, suppose because these people are poor and needy, we should give them a part of our stores—give it to them because they are unfortunate, and lack judgment. What is the thing to do? In our text the wise virgins flatly refused; and they gave as a reason for refusing, that there would not be enough left for them; that if they divided, the probability would be they would be in the same boat, and told them there was no other way for them to do than to go and buy, as they had done. Was it hard-hearted, unfeeling, unchristianlike? It is a very hard thing for me to refuse a favor; and it is especially hard to refuse a friend or a neighbor; but I have a great many times looked back, and have been obliged to decide that I had done a positive harm—an injury to some friend—by being too obliging, as the world calls it.

Whenever there is a revival of religion, there is always a great tendency to fall into the error of supposing that Christianity consists in being easy and obliging and liberal, and in giving to the poor; in helping folks out of tight places; but, my friends, if you do not look out, I am sure a great evil creeps in here. Perhaps one reason why our revival seasons do not result in more permanent good is because we do not encourage starting on a sound basis. One's sins may be forgiven, it is true; but I am afraid God does not forgive our sins until we have shown a manly spirit in the way of making up the wrongs we may have done to our fellow-men before we repented. It is well known about here that our institution is based and builded on godliness—at least, I try to have it so. Well, sometimes those who have applied unsuccessfully to me for work, have come out and united with some of our various churches; and after having come out, the question comes, if not right away sometimes after a time, "Now, Mr. Root, will you give me a place?" I have said before in these pages, that I am not afraid to take the risk of giving almost any girl or boy a place when I can be sure that such people are looking to the Savior, and trusting him; but I have been obliged to de-

cide by sad experience, that a profession is not enough to decide the matter. I want to see the individual and watch him a little. How quickly we can read human nature! It takes but a very little while—but a very few days, in fact, to tell pretty accurately where any man or woman stands, whether it be the things of this world they are seeking, or the kingdom of God and his righteousness.

Many of the bee-friends have tried giving brood to a colony having a poor queen, hoping to build them up strong, and make them self-sustaining. I have used this figure before, but it comes up to me so often I do not know but I shall have to refer to it again and again. The comb of brood produces its effect, and for awhile the colony seems to be a prosperous one; but the fact remains, there is no real good prolific queen at work backing up the new accession to the force of the hive. In a very little time we are forced to admit, that the colony is dwindling again, and running down hill, and no permanent good has come from the lift. It is the same in giving employment to one who has been the rounds here and there, and failed in securing a permanent place anywhere, just because of his improvidence. Worse still is the plan of making a donation, or taking up a subscription for some one who is able to work, but won't. The money given them produces the desired result for a little time, but the time very often seem to be exceedingly "little." The money is gone, and they are more destitute than before, more improvident, and feel less like going to work. Perhaps you think me hard and unfeeling. If so, take some money in your pocket and go around your own town; investigate carefully, and hunt up places where you may do good with this money; then go around again carefully, and look at the result. When we sow seed we expect it to bear a crop. The crop should be worth more than the seed sown; in fact, the harvest ought to pay expenses or more. The same way in giving money to the poor and needy. It ought to assist them in getting on their feet, and getting at least a little way toward being self-sustaining. No doubt money can be used wisely and judiciously in this way; but unless you are an old hand at the business you will do harm rather than good. You will probably conclude in the end, that the wise virgins were wise indeed in refusing to lend even a drop of their oil.

Well, what shall we do? Let these friends go to the county infirmary? Now, hard as it may seem, I have decided, over and over again, there was no other way. Please do not misunderstand me here. Widows and orphans are not what I am talking about. They do not have a fair chance with the rest of the world, and friends or relatives should by all means give them all the assistance they need. If a family of children is left without a father, of course they must be helped until they are able to help themselves. When the children get to be of the proper age they can pay their way; and the mother too, as a rule, can pay her way, and prefers to do it. We seldom see women too slothful to take care of themselves where they can do so, even though our parable does take the

sex for an illustration. Many women, I believe, work themselves to death in their anxiety to be independent and self-sustaining; and this reminds me that, as a rule, those who are deserving of assistance seldom ask for it. People who are crippled, or out of health, sometimes need assistance; still, a great many times laziness is called sickness, and I believe laziness often makes people sick. I have sometimes thought that where one has an earnest will, he gets well. We have instances all around us of people who recovered their health because of some new hobby or enterprise that enlisted all their powers of mind and body.

Our chapter opens with this expression: "Then shall the kingdom of heaven be likened unto ten virgins." You will notice that it is not only the things of this world that are to be given to the provident, and those who take forethought, but heaven itself; and the lesson teaches us that he who goes through the world, appropriating whatever comes near him, without thought or care, will find little mercy when the day of final judgment comes. The parable beyond the one I have taken, brings this out in a strong light, and it also shows us that sad fact in life, that he whose life has been all spent and wasted is always ready to throw the burden on the world, or on his greatest benefactor. The wicked and slothful servant, you will remember, began by ingratitude and abuse, with the vain hope to ease his guilty conscience. How natural is this! And please mark, friends, what a striking contrast is shown between this servant, and the one who had spent a life of doing good to his fellow-men. When the king said to those on his right hand, "Come, ye blessed of my Father, inherit the kingdom prepared for you from the foundation of the world," they were taken by surprise, and could not imagine what they had done to have merited such a favor, and such a great inheritance. They had been patiently bearing the burdens of the world; they had ministered to the sick, fed the hungry, given drink to the thirsty, looked up strangers, clothed the naked, and yet had forgotten all about it. In fact, they were not expecting any thing. I have sometimes looked out upon the world; and as I meditated, I was lost in wonder to see the wide, wide distance that lay between two who may be passing side by side on the street. One is vicious, selfish, greedy; he robs and plunders at every step. By example and precept he breaks down righteousness, godliness, and sobriety every where he can. His whole soul seems bent on self and lust. By his side may be one whose every act in life indicates a thirsting after righteousness—one who bears uncomplainingly the burdens pressed down upon him by multitudes like the companions by his side, and yet he does not know it. The one dreams not of the awful doom that awaits him, and the other dreams not of the reward awaiting the end of his pilgrimage. We do not know what becomes of the improvident servant, but we read this:—

Cast ye the unprofitable servant into outer darkness: there shall be weeping and gnashing of teeth.

Every human being has rights. The five wise virgins had prudently provided oil for their lamps. This oil was their own; it was right to do what they pleased with it. They had their busy cares, very likely, and perhaps did not think of, may be did not know of their improvident neighbors. I have sometimes thought that this right, belonging to every individual, was a sort of circle surrounding him, extending a certain distance, and this circle is his own premises. Nobody has any right to infringe on it. Even our smallest boy who comes to work here at three cents an hour has his circle of rights. The three cents which he honestly earns belongs to him, subject, of course, to his parents' approval. He is a man, to all intents and purposes. Nobody has any right to borrow his earnings if he does not choose to lend them; and those who are older ought to know better than to try to borrow from him. They have no right to take advantage of his inexperience, by asking him to loan his small earnings. A few times I have been obliged to be pretty severe on some who had a weakness for borrowing from their fellow-workmen, especially from some of the younger ones, who did not know they would not pay as they agreed to. A great many good people very much dislike to disoblige, and so lend against their better judgment. Sometimes when our wagon breaks down, the hands suggest going across the way and borrowing of our neighbor, who is a dealer in lumber, and has many teams. I know he would let me have a neckyoke or a wagon, or may be a horse, if I should ask for it; but the very reason why I dislike to ask him for any thing is because he is so very kind and obliging. Now, under the circumstances it seems to me I have no right to ask the loan of his tools, unless the circumstances are very urgent indeed. Once one of the hands, without my knowledge, went over and borrowed a neckyoke. A week or two after, I found it where it had been dropped. The hand who got it had forgotten to take it home, and our neighbor was too good-natured to come after it.

A little boy once got a bright new sled for a Christmas present. It was an extra nice sled, and he was proud of it. A neighbor borrowed it to get a sack of flour. He left it in front of the postoffice, or some such place, while he went in for his mail, and somebody stumbled over it, and in his anger kicked and broke it. The neighbor took the sled to a tin-shop and had it patched up with some pieces of tin, telling the boy it was just as good as ever. The boy did not think so, and he never cared for his poor broken patched-up sled afterward. His rights had been invaded. If any one prefers nice new things, without patch or blemish, it is his right, if he pays for them. The man who borrowed the sled was a Christian. A friend of mine had an old cutter which he had loaned so much that it was not decent to take the children to Sunday-school with. He bought a nice new one for the purpose. In order to get rid of the old one, as he did not care for two, he had it repaired and painted and varnished, so it looked quite respectable, and he did this *on purpose* that

he might sell it. Before the paint was hardly dry, his old friends wanted to borrow it. He was too easy and obliging to refuse downright, as I should have done, and off it went. Before the borrower got quite home, another man wanted it to go to a *temperance* meeting. When it got back from the temperance meeting it was marred, and broken in several places. The temperance-meeting man said he did not break it, and the first borrower said *he* did not break it, and he guessed it must have been so in the first place. As the last one who used it did not know where it belonged, it did not get home for a couple of weeks; the winter was then almost gone, and the cutter can not be sold until another winter. Those who borrowed the cutter were church-members, and the man who owns it is not. I have been for years trying to convince him that church-members are more reliable, as a rule, than people who are not. Do you wonder that his faith is small? Now, my friends, it seems to me that if we want to honor Christ the Savior, it is of far more importance that we avoid trespassing on the rights of our fellows than it is to make a *profession* of religion, or to be energetic and zealous in the *temperance* work. If you want to win souls to Christ, be careful how you heedlessly trample upon the rights of your easy and obliging neighbors. I do not believe it is a good plan to borrow, as a rule. When you are *obliged* to, remember the borrowed property is, as it were, a sacred trust. Keep your eye upon it, with tenfold more diligence than if it were something of your own; for by so doing you will honor the Savior in a way you can scarcely do otherwise. If it is injured, do not rest by saying it is as good as when you got it. Make it a great deal better. Let the world understand, and let the all-seeing Eye recognize, that you propose to go through this world leaving your fellow-men more than they had before you came along, rather than less. Never let it be possible for any one to say truly that you have been "reaping where thou hast not sown, and gathering where thou hast not strewed."

Some of you come to me for advice. Some of you ask me what you shall do to inherit eternal life. Well, now, if you value my opinion and judgment, it seems to me almost the greatest need is in the direction I have pointed out—in honoring God by letting the world see and know that you are not disposed to trespass on the rights of any one. This amounts in substance to what Jesus said: "Thou shalt love thy neighbor as thyself."

We have much trouble, as I told you before, here in our large factory, by borrowing tools, and heedlessly dropping them where they were used. One of my greatest cares is to keep an eye on this sort of work. We have one boy in our number (and he is one who has newly found the Savior) who has made up his mind to have tools of his own, so as not to trespass on the rights of others. One day I saw a brace and bit lying where he was using it, and asked him if somebody would not be wanting it. He looked up smilingly, and, with a little conscious pride,

replied, "Mr. Root, this is *my* bit and brace." On inquiry I found he had purchased with his earnings a little saw, two sizes of hammers, and some other tools that he needed often in his work, and was independent, you see. I told him if he would make a little chest for all his tools I would give him the lumber, and pay him for the time while he was making it. You see, you can honor the Master by having tools of your own, instead of wanting to borrow. People may be stingy of their tools, their cutters, their buggies, and may be of their horses, but it is their right. I like to see people who have the good sense to refuse to loan their things. I do not believe I should feel hurt if somebody explained to me that he would rather not lend something I asked to borrow; but I do not believe I shall be subject to such a trial, for I am not going to ask people for things when I am pretty sure they prefer not to lend them; or, if you choose, when good sense would dictate that they would better not lend them. A mutual exchange between neighbors is sometimes very desirable. Now, then, if you want to show your zeal for Christ, can you not show it more effectively in the way I have pointed out, than by any great amount of talk in public, or any strong profession. Remember what the king said of the careful and the provident:

Come, ye blessed of my Father, inherit the kingdom prepared for you from the foundation of the world.

NOT ALWAYS DEAD WHEN THEY APPEAR TO BE.

SOMETHING APPROPRIATE FOR THE PRESENT SEASON.

LAST evening I discovered that one colony of my bees were dead, or I supposed they were. It was a very small swarm, not over one quart of bees in all; they were clustered on three frames, and their stores were all consumed, so of course I at once pronounced it a case of starvation. Part of them were clustered naturally between the combs; the rest were on the bottom-board. I brought them up into the kitchen, took out the center comb, and on that found the queen. She is an Italian, that I bought and introduced last fall. I took her in my hand and breathed on her for about two minutes, when one of her feelers began to move; then I put a drop of honey by her tongue, and within ten minutes we had her in a cage, alive and smart.

We then turned our attention to the others. As yet they had shown not the least signs of life. We breathed upon them, and held them where it was warm, also sprinkled some thin honey among them. Soon one after another began to move, and within half an hour they were so lively we were obliged to put them into the hive and close them up. This morning I found at least three-fourths of them alive, and they appear to be none the worse for their nap.

Now, Mr. Root, do you ever know of a case where bees were so far gone as those, and still live? It is my opinion, that a great many bees are destroyed that might be saved by a little pains on the part of the bee-keeper who imagines his bees are dead when they are not.

A great many colonies are starving to death this winter, in this county. I know of 50 or more that have starved, and it seems really too bad when it costs so little to keep them alive. My bees have been in the cellar 120 days already, and but very few have died, probably not more than a quart in all. The most of them have granulated sugar in cakes over the tops of the frames, in case they run short of honey.

J. R. BALL.

Knowlton, Ind., Feb. 28, 1885.

Friend B., we have had a good many such reports; but as the matter comes up every spring, it is a good plan to have it repeated. You will find the same thing mentioned in the A B C book, and, if I am correct, a colony may be saved after they have been in this condition for 24 or even 48 hours. I have never been able to discover that they were in any way injured by this nap of apparent death. It almost always occurs when bees are out of stores, or nearly out. Sometimes when candy is laid over the frames, the cold prevents them from using the candy, especially where the colony is weak. Where a colony has candy over the frames, broken up into small pieces the size of a hickory-nut, or smaller, they will usually get enough of it melted and stored in the combs to last them through any freeze we may have in March.

GLEANINGS IN BEE CULTURE.

EDITOR AND PUBLISHER.

MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clipping Rates, See First Page of Reading Matter.

MEDINA, MAR. 15, 1885.

Then shall he answer them, saying, Verily I say unto you, Inasmuch as ye did it not to one of the least of these, ye did it not unto me. MAT. 25:45.

CLOVER FOR SPRING SOWING.

We have a splendid lot of alsike and mammoth red, or peavine. A sample of seed will be sent to those who are unacquainted with the peavine. Clover seed by the bushel can be sent safely by freight, and is much cheaper than by express; but you will have to order it some little time before you need it for freight is, I believe, apt to be slow.

DISCOUNTS BETWEEN NOW AND APRIL 1.

DISCOUNTS on section boxes, comb fdn., and comb-foundation machines, will be extended as in our last issue until April 1. Of course, demand and supply will decide whether these discounts can be carried after that date. We can fill any order for almost any thing now, promptly; but the season is fast approaching when delays are likely to be almost unavoidable.

SECTIONS DOVETAILED ALL AROUND.

THE "odd-size" business begins now to make trouble again, as is usual about this season of the year; and when we said we would make sections

dovetailed all around, at the same price as the one-piece section, we forgot about odd sizes; and at present it looks as if it could not be done. That is, we can not make four-piece sections, odd size, nearly as easily as we can make one-piece sections odd size.

WHO FIRST STARTED IT, AND WHOSE INVENTION IS IT?

SINCE our talk about moral patents, this thing seems to be coming up a great many times; and in the *Apiculturist* for February our friend P. C. Elwood takes the *A. B. J.* to task for copying the plan of the Question Department, claiming this to be original with the *Apiculturist*. We would remind friend Elwood, that this idea of getting prominent men to give their opinions collectively on certain important subjects was a special feature of the *Bee-keepers' Instructor* in 1882. We were so much pleased with this idea at the time it came out that we commented on it, and copied a page or two. See GLEANINGS for July, 1882, page 230.

DECLINE IN PRICE OF TIN.

THE price of tin, per box of 112 sheets, suitable for separators and honey-cans, will be, until further notice, \$5.50 instead of \$6.00. Tagger's tin, a good deal thinner than the above, which we now use expressly for separators, unless otherwise ordered, \$5.00 per box. This is considered preferable to ordinary tin, because it conducts away the heat of the hive much less, on account of its thinness. It must be handled much more carefully than ordinary tin, and is not suitable for honey-cans, unless they are very small ones. Best charcoal IX tin, \$7.50 instead of \$9.00. All the above is 14 x 20 in size, and 112 sheets in a box. These prices are for tin on board cars in Philadelphia.

WATERBURY WATCHES FOR 1885.

A STILL further improvement is out, and we have just received a gross of them, and the manufacturers have given us an arrangement whereby we are enabled to send GLEANINGS one year to every customer who purchases a watch at the full retail price of \$3.50, but we are not permitted to sell a watch any cheaper where GLEANINGS is not wanted. We can, however, do this: You can have two watches for \$6.00; or anybody who has already purchased one Waterbury watch can have another for an even \$3.00. With every watch, we now send a pretty nickel-plated steel chain. On the chain is a hunter's whistle. This pretty little chain will be only 5 cts. where it is wanted without the watch.

THE HEDDON HIVE AND SYSTEM.

At the present writing we have received orders for just two Heddon hives. I am a little surprised at this; but I presume the reason is, that so many of us are loth to bring a new hive or fixture, that does not correspond with our other hives, into the apiary. Besides, every advantage that friend H. claims, can be secured with the Simplicity and chaff hives, unless it be the 8-frame feature. When these new things come up, I think it is very much better to test them with the hives we have already in use, rather than to start new hives and new frames. I am very sorry indeed that friend H. insisted on a frame 17 $\frac{1}{2}$ instead of 17 $\frac{3}{4}$ long. Great confusion is going to result here in spite of us. We do not remember that we have received an order for a Langstroth frame 17 $\frac{3}{4}$ long, except twice, and

we shall make our hives and frames for the usual 17 $\frac{3}{4}$, unless our customers specially state that they must have them 17 $\frac{1}{2}$.

BEE-KEEPERS' CONGRESS AT NEW ORLEANS.

IN view of the fact that friend Newman has prepared a very full and elaborate report of all the proceedings there, including even the names of those who were present, I do not think it would be best for us to attempt to repeat the same in GLEANINGS. If you are not a subscriber to the *A. B. J.* (it seems to me every progressive bee-man ought to be), friend Newman will doubtless send you the two numbers containing the report, on receipt of ten cents. Where there is so much matter for our journals, and so much good matter that we can not find room for, it does not seem to me advisable to have one journal a repetition of another. I know there is something to be said on both sides of this, but I believe the majority of our readers will agree with the above.

REVERSING DEVICES.

THESE still come in considerable numbers daily. C. H. Deane, Versailles, Ky., and John Consor, Glen, Kansas, both claim that we infringed on their inventions in my wire reversing device, as given in the last number. I confess I have this far: They sent such an arrangement made of sheet iron, and mine is made entirely of wire. I do not like the sheet iron, and would not use it, but I like the wire. Well, if mine is an infringement, the question arises, "Which of the two is entitled to precedence?" On investigation I find the postal cards which each one wrote when he sent his device, are dated exactly the same—Feb. 11. Friend Deane claims, however, that he is still ahead, for he invented and we illustrated something quite similar, for another purpose (see illustration in GLEANINGS for March, 1882, page 180). I admit the similarity, and yet the device alluded to was made when no such thing as reversible frames was thought of; nor was it intended, nor is it adapted, for the purpose. Perhaps we had better await further developments a little.

WHEN ORDERING THE ABC BOOK, SAY WHICH YOU WANT—CLOTH OR PAPER.

ALMOST daily we have one or more orders for the A B C book, without saying which they want—cloth or paper edition. It is true, we can sometimes make a guess by the amount of money inclosed; but since we have offered the cloth-bound book postpaid for a dollar to those who have already bought one, the price sent does not help us much. We began sending the paper-covered one to those who sent a dollar; but, oh my! what a breeze it made because we did not remember they were entitled to dealers' rates, the writer often saying that he would not take a paper-covered book as a gift, and back it comes at our expense. Then I told the clerks to send cloth-bound in every case, unless the writer said plainly, paper covers. This seems to be the lesser of two evils; but for all that, a great many say we might have known by the amount of money sent what was wanted, and they accordingly refuse to pay the 25 cents balance, or suggest returning the book at our expense. Now, friends, what can we do, unless you say in your order, cloth-bound or paper-covered, and also state whether you are entitled to dealers' rates or not? We are very anxious to please, but we do not like to be scolded when we are doing as well as *anybody* could do without fuller instructions.

A Splendid Offer.

To all those who will send us **at once** their subscription to the

American Apiculturist.

For one year \$1.00 and \$1.50 extra, or \$2.00 in all, we guarantee to send a choice Italian queen worth \$1.50. These queens are bred for us by a careful and reliable queen-breeder. We also give away to all those who will send us their address, plainly written, an interesting and valuable little pamphlet, the "Bee-Keeper's Companion." Send us your address **at once.** Address

NOTES FROM THE BANNER APIARY.

NO. 64.

RAISE FIRST-CLASS HONEY.

EACH year, when attending the bee-keepers' convention at Chicago, I have spent half a day among the commission merchants of South Water Street, where the sidewalks are piled full of barrels of apples, nuts, beans, and onions; baskets of peaches, grapes, pears, and plums; coops of cackling poultry; piles of dead partridges, quails, and ducks; boxes of cheese; firkins of butter, piles of crates of honey, etc. Only a narrow passageway wide enough for one person to pass is left through the center of this endless profusion of "good things." This passageway is intersected in front of each store by a passageway entering from the store door to the edge of the sidewalk. Inside, the stores are filled so full that I felt to wondering how the sidewalks could be cleared at night. The street is *literally filled* with trucks and drays engaged in carrying away and bringing in the varied products. The passageways upon the walk and in the stores are alive with a pushing, bustling, eager, but good-natured crowd of sharp and experienced buyers. It is interesting to stand back out of the way and watch the proceedings. Whatever is attractive commands immediate attention; but it must *bear inspection* before it can be sold at a *high price*. Buyers expect that the red cheeks of the peaches will be turned uppermost and against the cracks in the baskets, but they want no culls in the center. The nice-looking apples disclosed by the removal of a barrel-head do not satisfy the would-be purchaser, so out comes the hatchet that always hangs at the belt of a

"helper," and three or four holes are cut through the side of the barrel. No matter how nice the honey may appear when seen through the glass side of the crate, this same ever-ready little hatchet must needs pry off the cover to the shipping-crate, and allow the inside sections to be examined. My friends, it is through such an ordeal as this that your honey must pass, and under such circumstances that it must be sold, if sent to a commission merchant. If it is second class, it will stand a second-class chance of being sold, and, when sold, must be sold at a second-class price.

When in conversation with one of the commission merchants in regard to the advisability of sending my honey there to be sold, he said, "If it is white, the combs straight, and the sections well filled, I think we can sell it for you at a good figure; but if it is dark, or even a little 'off,' or if the combs are not well finished, don't send it. You had better sell it at home for a shilling a pound—yes, for whatever you can get for it." He then took me back into the store and showed me some third-grade honey put up in third-grade style. The crates were made of inch boards, and held about 50 lbs. each. The lumber was planed, but was somewhat weather-beaten. There was an opening covered with glass upon one side of each crate. These openings had been cut out with a coarse saw, and no pains had been taken that they should be well proportioned, or even that the angles at their corners should be right angles. The honey was dark, and there was no space between the honey and the cappings; the combs had a yellowish cast, and the propolis had not been cleaned from the sections. That honey had stood there *one year*, and the consignor had complained bitterly because the consignee was "so slow." This is, of course, an extreme case; but I saw all

grades from this up to straight, neat, well-finished white combs, in smooth white sections, crated in small crates of clean white basswood. There was but little, however, of the latter; for it had been bought up "too quick."

Scattered about in the heart of this great city, Chicago, are the stalls of fruit-venders, and it is interesting to see how well the owners of these stalls have learned that *appearance has a market value*. They never buy any apples except red ones, and they rub and polish these with a cloth until they shine like mirrors. Their plums, pears, peaches, and grapes are always placed with the *bloom uppermost*. Some of them will take a small round peach-basket, and fill it with a mixture of grapes, plums, peaches, pears, and apples. These fruits are so artistically placed as to form a perfect picture, and over them is fastened a piece of pink mosquito netting, which gives the whole a hazy, mazy, far-away sunset ruddy glow that is very alluring—perhaps too much so. The mind knows that the eye is deceiving it, but the deception is so pleasant, and 50 cts. changes hands, causing scarcely an economical twinge of its owner's conscience.

Now, on the other hand some people, mostly producers, put their products on the market in a condition that is absolutely unattractive, if not disgusting. Why they do so is beyond my comprehension. When will honey-producers learn that *appearance has a market value*? The honey stored in bulged combs, in weather-beaten sections uncleaned of propolis, and crated in an uncouth manner, may be just as sweet as any honey, but it will *never* sell for so much as that stored in straight combs, in white clean sections, and crated in neat, clean crates. It costs but little more to raise strictly first-class "gilt-edge" honey, that will sell for from one to three cents per pound above market price, and sell quickly at that, than it does to raise "stuff."

The first step necessary in raising first-class comb honey is, that the honey be *white*. This depends upon the source from which it is gathered; hence the bee-keepers must be located where the main honey-producing plants furnish white honey. Next, it is imperatively necessary that the sections be smooth and white. To save (?) one or two dollars in buying 100 second-class sections is the very poorest kind of economy. Get the *best*. The white poplar sections are superior to all others as regards whiteness, smoothness, and hardness. I have been quite enthusiastic in explaining how to dispense with separators, and have shown by my *works* that first-class honey *can* be raised without them; yet, if any one does not wish to comply with the conditions that I gave, or having done so, still does not succeed, then let separators be used *by all means*. We *must* have straight combs. Unless the tiering-up system is used, it is necessary to remove the sections as soon as finished, otherwise the combs become travel-stained. I have seen considerable honey placed upon the market, in which a few cells along the lower edges of the combs were unsealed. No honey can rank as first class in which the cells are not all sealed, or the sections are daubed with propolis. Too much attention can not be paid to crates. Even second-class honey will sometimes sell quite well, if nicely crated. This matter of crates is becoming so important that it is even mentioned in the market reports (see what A. C. Kendel says in his market report in GLEANINGS of March 15th). The crates should be of thin white lumber, and

kept as clean as possible; in fact, I have sometimes thought of covering them with thick paper when shipping them, that they might reach the market with their immaculate whiteness unsoiled. Of course, holes should be cut in the paper where it comes over the glass.

Please don't paste a great placard upon each crate, announcing that "this honey is from the apiary of the great Mr. So and So, of So and So." The first thing the commission merchant will do is to soak and partially scrape off these placards, thus giving the crates a ragged, dirty appearance. You had better send to your commission merchant for a stencil-plate. This plate will have 3285, or some such number, artistically woven in with the address. That is *your* number, the number of *your* stencil, and is recorded in a book opposite your name and address; and when your honey arrives the merchant will look up 3285, and find that the honey belongs to John Smith. When marking the crates, don't daub the blacking all over every thing, but try to make the marking look as neat as so much printing.

First-class comb honey must be first class in appearance as well as in quality; in fact, so far as its sale is concerned, the appearance is of more importance than the quality. Not so with extracted honey, in which quality is fully as important as appearance. Comb honey is a thing of beauty, is used as a table ornament as well as a delicacy, while extracted honey can be made no more ornamental than molasses or syrup. The only way in which an attractive appearance can be given to extracted honey is to put it up in attractive packages. The only requisite in raising first-class extracted honey, aside from the source from which it is gathered, is that the honey be thoroughly ripened. Some of our best apiarists assert that honey extracted as soon as gathered, before it is ripened and sealed over, and then ripened or evaporated by exposure to the air or to the sun's rays, is as good as that ripened and sealed up in the hives. Others, among whom is the writer, think no honey is so rich, sweet, and finely flavored, as that ripened and sealed up in the hives.

Now, if in order to have extracted honey first class it *must* be sealed over, it appears very foolish to raise it. We take a frame of sealed honey from the hive. Now, if this honey had been stored in *sections*, the honey would have been worth 15 cts. per lb.; *now* we must extract it and sell it for 8 cts. Of course, the comb is left; but, see here: the honey and comb weigh 6 lbs.; and if in sections would sell for 90 cts. We extract 5 lbs. of honey and sell it for 40 cts.; is the empty comb worth half a dollar? "But," says some one, "we can not get so much honey per colony when it is stored in sections as we can in frames." Beg pardon, my friend, that is simply because you don't know how.

W. Z. HUTCHINSON, 64—94.

Rogersville, Mich., March 29, 1885.

And so, friend W. Z., you are going to "sit down on" extracted honey, are you? Well, all right. Your article is certainly a most excellent one, and hits the nail right square on the head. If there is any mistake anywhere in it, it is in that last paragraph, and may be there is not any there, although I think there may be circumstances under which one can raise extracted honey to a better profit than comb honey. We

hear of a good many markets where they get about as much a pound for one as for the other. Under such circumstances, the extractor is, without question, ahead. I am glad to notice that your article includes a broader field than bee culture alone. It is getting now so that in every department of life one who is careless and slipshod must take a back seat, and work for small pay. In our new book on potato culture, which our printers are now at work on, friend Terry mentions passing a neighbor on the road while he was hauling his fine large potatoes to market. Friend Terry had sold out his whole crop at a big price, but his neighbor was drawing back home a load of small scabby potatoes, because the market was overstocked. As they stopped to talk a minute, this neighbor remarked: "Well, Terry, you are a lucky dog." The author of the book replied that there wasn't any luck about it; it was simply hard work and common sense.

PURE GERMAN CARP.

Directions and Instructions.

FREEZING OVER.

Concluded from last number.

THIS is something that must be prevented, in order to save the fish, more especially in the Northern States. If there is a strong spring, or if fed by a tile ditch that affords a strong stream, there is no danger of the freezing injuring the fish, unless it is extremely cold; then they can be kept open by using the ax twice a day. A plan that will never fail is this: Where your bank is the most suitable, cut a ditch near the bottom into the bank far enough so that a perpendicular line will make the top about four feet above the high-water mark in pond; then take tile or box; run it horizontally, forming an elbow, then perpendicularly. To illustrate, see drawing.

FIXING A CARP-POND SO IT CAN'T FREEZE OVER.

- A, high-water mark in pond.
- B, bottom of pond.
- C, the bank.
- D, the air pipe or box.
- E, height of water in pipe.

It being about four feet to the water from top of ground, it will never freeze, therefore the air will be passing under the ice in the pond all the time. In a very cold climate the pipe can be run further in the bank, which will make it deeper to water from top of tube. As soon as you get the banks, levees, and dams completed, set out peach, cherry, or willow trees, and sow grass seed of different kinds.

Now I believe we have you ready for the carp. I would advise you to get the three kinds. They will not mix, and when prepared for the table there is no

perceptible difference in them. Some prefer the scale, because they are easily cleaned. The mirror is the most rapid grower.

CARE OF CARP.

They are naturally vegetable feeders, but will not disdain worms, larvæ, and other animal substances. Where there is not an ample provision of vegetable food, the fish may be supplied with crumbs of bread, leaves of cabbage, lettuce, etc., sweet or Irish potatoes, or with corn, rice, and other cereals, either entire or ground, and which should be boiled in plain water before administering. No more food should be given than the fish can conveniently consume without leaving any to sour and spoil. You should endeavor to feed always about the same time, and at the same place in the pond. If you wish to teach them to come at a signal, choose some sound or whistle, and always make the same before feeding them. After the cold weather sets in they need no feed, as they bury themselves in the mud whenever the temperature of the water renders it necessary. In this condition they should not be disturbed. I have found by experience that about 12 o'clock at noon is the best time to feed, for two reasons. 1. The water is in the best stage; 2. We feel more like spending a few moments just after dinner, than at any other time in the day. And I tell you, my friends, when you get carp you will find more enjoyment in feeding them and watching them eat, than in anything you ever watched before. Think of seeing them come up, rolling over one another after the food, acting like so many pigs.

The carp, as I told you in my previous article, are not carnivorous, and should not be in a pond with other kinds of fish. They do not destroy their young, unless almost starved. Don't put them in with other fish. Be sure your pond is clear of all fish, or any thing that would destroy either spawn or carp. If you have fish in your pond, drain it and clean out the mud. If you can not do that, then drag the pond with a good seine until you get it clean. If this fails, the last remedy is to get some experienced hand to blow them out with dynamite. I am opposed to this, but it is the last resort.

The ponds in which carp are placed should have a muddy bottom, and be well provided with aquatic plants, especially such as produce seeds that drop into the water when ripe. The fish should have something to attach their eggs to, such as leaves and stems of living plants in the water or grass, and brush around the edge of pond, where the water is not too deep.

Now you have the pond completed, and the carp in it, the next thing is to get them out. Well, if you want to get out a few small fry for your neighbor, use a small minnow seine. Feed your carp, then run around with one end of seine; but you must be quick and still about it. If you do not catch enough the first time, wait an hour or so, being still, then try again, and so on until you get what you want.

CATCHING THE CARP.

I have a pole, line, and hook. I bait the hook with stale light bread, which floats on the surface of the water, and the carp come to the top to suck it down. As soon as they feel the hook they start to run, and I then tighten on the pole a little, then slacken and play with them until I worry them out, and land them without further trouble. After catching one in this way they become very wild and

timid, and it is a long time before I can get them to show themselves again. Always bait two or three spots if you can, so that, when the fish are alarmed at one you can rest it and go to another, casting in a few handfuls of bait before you leave, to bring them back while you are gone. Carp will take as bait, worms, gentles, wasps, grubs, plain and sweet paste, boiled green peas and potatoes, as ground bait, but I have better luck surface fishing, and I use bait that will swim. The great secret in carp-fishing is to keep quiet and fish fine. Carp are called the crafty fish, as sly as a fox. On the slightest noise or jar on the banks they will go to the deepest water with great rapidity.

In conclusion, my friends, I have endeavored to give a plain and comprehensive description of the carp business; and if I have overlooked any points, or should you wish to ask any questions in reference to the carp or ponds, inclose a stamp and I shall be pleased to answer any thing in my power, and will take great pleasure in doing so.

Andersonville, Ind., Feb. 6, 1885. W. S. KALER.

Friend K., it seems to be a disputed point as to whether letting the pond freeze over does harm or not; but your ingenious device makes it quite easy to give the carp access to air at any time. Within a few yards of the shore of our carp-pond is an old well, built when our grounds were used for the Medina fair. I can reopen this well, lay a six-inch drain tile from the bottom of the carp-pond, or from the deepest place, and carry it into the well on a level. The fish can then go through into the well whenever they like, and the well will never be frozen over. Mr. Peirce, the author of our book, objects to traps around the carp-pond, as they keep off the suh; and in our latitude we want every bit we can possibly get; in fact, it is pretty well proven that the warmer the temperature of the water, the better; and excellent results have been obtained where the heat was carried by artificial means to a higher point than we ever get during the hottest summer weather. I do not believe I should want to have my fish frightened by letting anybody catch them with a hook and line.

HOW TO DO BUSINESS IN SUCH A WAY AS TO AVOID COMPLAINTS.

A LITTLE SKETCH, AND AN IMPORTANT MORAL.

SOME years ago a merchant in the city of New York took a notion to bee culture. In furnishing him supplies, some mistakes were made. In writing about it he made a remark something like this: That if I would come to New York he would show me a business house that made sales to the amount of something like half a million yearly, and yet they managed it all almost without a mistake, or a complaint from a single customer. I give the above from recollection, so I may not have got it right, but I have often thought of it. Can anybody conduct his business so thoroughly, carefully, and prudently, that nobody can find any fault? Could we have buyers and sellers who are not liable to human weaknesses, may be it could be done; but, alas! we are all human—exceedingly human, I sometimes

think. Now, I want to give you a history of a little transaction, and I do it simply to point a moral in one direction. Here is the story:

January 12 we sent a customer about \$25.00 worth of bee-supplies. After he had checked them off he writes as follows:

I received the three packages of goods by railroad in due time; and upon counting the metal corners I find that only 24 frames are supplied with corners, and two parts of another frame; that is, the upper corners that frame hangs on are all that came with the packages. As there should be fifty, there is a mistake somewhere. The packages all came in good order—nothing had been disturbed after they were nailed up until I opened them, and nobody has had any thing to do with them but myself, so I know what I am writing about. Now, I can't do without the corners, and you must send them by the way that they will come cheapest, either by mail or express; and if you say I must pay for them, send me amount by mail, and I will forward whatever you say. R. B. HOAG.

Lockport, N. Y., Feb. 6, 1885.

You will notice that our friend is not at all complaining nor difficult to please; he says he will pay whatever we say. From his writing you would also decide at once that he is a man of experience in such matters, and one not liable to be mistaken. Investigation, however, showed that the goods were put up by our most careful packer—a man who stands at the head of our shipping business, and who has been trained to it from childhood. When the clerks find a complaint has been made in *his* packing, they always write back, stating the case, and asking that further search be made. Our customer, however, insists he is right, as you will see by the following postal:

Only one package of metal corners with the goods. All have been taken out; number as stated before is all that there was in package. Please forward the rest and oblige. R. B. HOAG.

Lockport, N. Y., Feb. 12, 1885.

Here are two good men, right squarely against each other. I told the girls to tell "Bert" (Bert is the boss of the packing-room, whom I have been telling you about) he need not pay the postage on the missing corners, because his mistakes were so very rare that I could well afford to pay for them when they happened. But I now find written across the postal card, "Stood it in spite of us," which means this: Bert said that he preferred to pay the postage; that he would rather do so, as it would teach him to be *still more* careful. It gives me a pleasant thrill to see this, because these two men, each of them, agree or prefer to stand between me and loss. This is what I call a real Christian spirit. It is a matter of only a few cents; but when we learn to dispose of matters involving only a few cents, with a good spirit, we shall be able to manage greater matters. I was quite willing to pay the postage; friend Hoag was quite willing to pay the postage; friend Bert was quite willing—or, still more, he good-naturedly insisted on bearing it himself, because he *might* have been at fault. Now for the sequel:

I write to you to make acknowledgment, and to restore to you what I supposed you had left out in my order to you several weeks ago. You will remember that I supposed I was short 25 metal-corner sets for frames in bee-hives. I have just discovered that one package of corners, as I took them out of packing-box and put them in a tool-chest, got shoved under the till of the chest, out of sight. It was some time after I unpacked goods before I discovered that I was short; but before I wrote you I made search to be sure, but I could not make out that I had the goods. I of course wrote you in good faith. Now I have found the package by overhauling and looking after something else. Now I send you for corners, 50 cts., and 25 cts. postage, and I also ask your pardon for the blundering way I have done this business. I did it all myself, without laying it to boys or agents. R. B. HOAG.

Lockport, N. Y., March 16, 1885.

Now, one lesson from the above is, that it shows how very easy it is for even the best of us to be mistaken. Another point: How can I, with a clear conscience, insist that any clerk shall pay heavy postage or express charges on goods our customer declares the clerk did not put in? Think of taking a poor hard-working boy's or girl's money when neither of them is in the least to blame; and yet I fear I have done that in times past. Last, but not least, may not the above prove a lesson to every one who receives goods and unpacks them? Why, I have sometimes thought I would give almost any thing for a clerk who would do exactly as I told him in this respect. With the years of experience I have had in the business I will say to them,—

"My friend, before you open that package, get a clean table, without any thing on it, and be sure you do not place a single article anywhere else than on that table. Don't take your box or barrel away until you are perfectly sure every article has been carefully and plainly checked. If the package is so large that it must be spread out on the floor, get a clean floor; do not have any rubbish anywhere near you."

Now, in spite of all these instructions, young people and old people, day after day, keep saying such a thing is "all gone," "wasn't in the package," etc. Our children learn it in youth by coming downstairs, and saying, "Mother, I can not find it anywhere; I looked everywhere you told me, and it is not there at all." Mother takes the child by the hand, leads it upstairs, and points to the article. "Where can your eyes have been when you came up here?" Did you ever see children do that way? Well, now, my friend, you want to get that child out of that heedless, shiftless way of doing, or it will be the curse of its life. Drill these little ones to be careful and thoughtful by line upon line and precept upon precept. Make them understand and comprehend that a careful boy or girl, and an accurate, reliable boy or girl, is worth her weight in gold; whereas the blundering kind that have eyes and see not, ears and hear not, are a clog and a hindrance to themselves and everybody else. I once heard of a little girl who said she had an excellent "forgettery." Poor child! There are whole families just like her. Now, then, friends, old and young, who among us is going to excel in this line of being careful?

SIMPLICITY CRATE, MOORE'S STYLE.

Made to go Inside of a Simplicity Hive.

FULL INSTRUCTIONS HOW TO MAKE AND HOW TO USE IT.

THIS crate, which might also be called the Heddon crate adapted to the Simplicity hive, is shown in the cut below. This crate is exactly 14½ inches wide by 18½ long. The sides are rabbeted in so as to make room for the three partitions as well as the end-boards. All of the partitions are ½ inch thick; the end-pieces 5-16 thick. The sections are supported by a strip of tin tacked along the bottom edge of each partition. These strips of tin are ½ inch wide by 13½ long. The end ones are folded in the middle at a right angle, and these are tacked against the lower ends of the end-boards, as will be seen by the cut.

CRATE FOR SECTIONS TO GO INSIDE OF SIMPLICITY HIVES.

The end-boards are 4½ wide, while the central partitions are only 3½. The partitions are nailed at such height as will bring the sections even with the top of the case. This brings their bottoms the regular bee-space of between ¼ and ⅝ of the bottom edge of the crate. We prefer the bee-spaces under the sections; because if any one should make a blunder, and set the cases right on top of the brood-frames, the bee-spaces would be all right. If you want to use the Heddon honey-board, or one made Heddon style, to fit the Simplicity hive, the honey-board lies on top of the brood-frames, and the crate goes on top of the honey-board.

You will notice, we do not use a *sunk* honey-board. The reason of this is, that the side-boards of our Simplicity hive rise above the tops of the brood-frames far enough so that a *sunk* is unnecessary in the honey-board. If you want to tier up these cases, one can be placed right on top of the other, as high as you choose, and Simplicity hives slip right over them, protecting them from being chilled cold nights, and from the extreme heat of the sun during sultry days. To get the sections out, turn a case over on a table, then strike it gently on a couple of strips of wood (two top-bars of a frame, for instance), having these top-bars placed so as to strike each on the edge of the crate. As I have explained before, this crate holds 28 1½ sections, or 32 seven-to-the-foot sections. For nailing these crates together, we need 16 ½-inch wire nails; 21 ¾-inch wire nails, 18 1-inch, and 16 1½-inch.

DIRECTIONS FOR NAILING UP THIS CRATE.

You will notice that one edge of the sides and ends is smooth. This edge goes up.

First nail these pieces together with the 1½-inch wire nails, four in each corner; then slide the thin middle pieces into place. The lower edge of these should be just 5-16 of an inch from the lower edge of the side-piece. This can be done very easily by having a gauge-block or a piece of wood, say 1½ inch wide, 5-16 thick, and 12 in. long. These middle pieces are to be nailed with 1-inch nails. The strips of tin are to be nailed with ¾ nails; and those partly folded, with ½-inch nails, and clinched on the outside. Care should be taken, when nailing on the strips; for unless a board is placed for them to rest on, they are liable to move.

PRICES.

Single crate, nailed up, 20 cts.; 10, \$1.80; 100, \$16.00. Price in flat, singly, 16 cts.; 10, \$1.35; 100, \$12.00. These prices include the necessary strips of tin, and nails for nailing them up.

There are two objections to using the above crate in place of the combined crate advertised in our price list. The first is, that separators can not well be used in connection with them, or, at least, it will be so much more machinery to make and use a separator for every section. If you are going to use this crate, make up your mind to dispense with separators. Second, the bees have access to the bottom of every section. Our Michigan friends claim that the use of the honey-board prevents any wax of any account being put on the bottom-boards of sections. I would advise using these cases with 32 sections, seven to the foot. If you want to tier them up, of course you will have to have open-top sections; when not tiered up, just spread your enamel cloth over the top. If it does not lie down close, put a board on it until the bees fasten it. In tiering up, put this same enamel sheet on the upper tier.

I think these crates will answer very well for sending sections to market; and in lieu of a better case they will do to retail from. The partitions have the effect of holding sections very true and square. This is quite an item with the one-piece sections, for if they are true and square when the bees commence working in them, they will remain true and square after they are filled.

WIRE CLOTH FOR DIFFERENT PURPOSES, AT A LOW PRICE.

WIRE CLOTH FOR POULTRY INCLOSURES, AS WELL AS FOR SCREEN-DOORS.

AN enormous trade in wire cloth has started up since the job lots we have purchased. In fact, so many orders have come for the same lot that we induced a large manufacturer of wire cloth, by taking, at a single time, between \$500 and \$800 worth, to furnish us regular first-class goods at the same low figure we have been giving; namely, 1½ cts. per sq. ft. But in order to furnish it at this price it must be sold in whole lots, running from 100 to 400 feet in a piece, and running from 12 to 40 inches in width. This wire cloth is just the thing for screen-doors, for confining bees, or for any thing of the sort. As soon

as a lot is received, a list of the widths and number of feet in a piece will be published.

Well, while we have been about it we have also secured a very low figure for galvanized wire netting for poultry inclosures. We give a cut of this below:

GALVANIZED WIRE NETTING FOR POULTRY INCLOSURES, ETC.

This wire netting comes in rolls 150 feet in length and 4 feet in width. This would give 600 sq. ft. of surface, and we are enabled to furnish it at the low price of one cent per sq. ft., or \$6.00 for a piece. Staples for fastening to the posts are 20 cts. per lb., and a pound contains about 400 staples. The posts to hold it should be not more than 10 ft. apart, and it should be set in the ground at least 2 ft. You can put down a top rail, if you choose, but the selvage edge of the netting makes a pretty strong fence; and as the fowls can not see it they can not tell how high to fly; and after being bumped down several times they usually give it up. In putting it on the posts, draw the top of the netting tight, and afterward draw the bottom down and fasten that. You can put a board a foot wide along the bottom, if you choose. This will prevent small chickens from getting through, and makes the fence one foot higher. One advantage this netting has over wooden pickets is, that it does not catch the wind as they do, and therefore the posts are not so liable to be tipped over; besides, it presents a very much more ornamental appearance, as you will see by the cut. The meshes are two inches across; and where the wire crosses it is securely soldered together, for the whole fabric is immersed in melted zinc after the whole is woven together. The size of wire used is No. 19. This galvanized wire never rusts, so it will last a lifetime, unless it is damaged by carelessly running into it. If you want to make division fences, so as to keep different breeds from the same yard, it is better to have a board at the bottom at least one foot wide, so the fowls can not be gossiping through the wire, and pecking at one another. You will notice that one roll makes a yard nearly 40 feet square, and this is plenty large enough for 20 or 30 fowls. Another advantage this netting has over wooden pickets is, that you can see what is going on inside so readily. The wind, also, has free access, which is quite an item during sultry weather. It should be shipped by freight. The weight of a single bale is about 50 lbs. It may be shipped from here or from New York, as may be convenient.

AN IMPROVED DRONE-EXCLUDER.

SOMETHING TO LET THE DRONES OUT BUT NOT IN.

DURING the past year several inventions have appeared, to permit the drones to get out of the hive without any trouble, but arranged in such a way that the perforated zinc shall permit only the workers to return, making the device more automatic than it is, using only perforated zinc alone. One of the best of these is friend Noble's device, shown below.

NOBLE'S DRONE-EXCLUDING DEVICE.

You will observe, that at the lower edge of the perforated zinc a series of little doors is hung by a light hinge on a slender rod of tinned wire. These little doors are just about large enough to let a drone pass through, and they are made of tagger's tin, in order to have them very light. That they may open outward and not inward, the door is made to be a little long—that is, it projects below the edge of the perforated zinc, so that, when the zinc rests on the alighting-board of the hive, the little door stands sloping outward. We will now let the inventor describe it.

I mail you an invention of mine that I call a drone excluder. I should be glad to have you pass your opinion upon it. To use it, place it at the entrance of the hive, with the wire or hinge side out. You will observe that the doors are about one twentieth of an inch longer than the space, causing them to stand out at the bottom; and as the drones come pushing along they will raise the door and pass out, but can not enter again. D. C. NOBLE.

Larwill, Ind., Feb. 11, 1885.

The obstacle to the correct working of the machine would be rust, if left out during storms. This might be partially remedied by making the doors of thin sheet brass; but I am afraid that even brass would in time get to be rusted fast. Perhaps zinc rolled very thin might answer; but even zinc would rust enough to stick those light hinges. The inventor does not say how much he has used it, nor for how long a time. We shall be very glad indeed to hear from some one who has made use of these machines during a whole season. It seems to me something quite similar has been described in our pages, but I can not now place my hand upon it.

BROOD-REARING WITHOUT POLLEN.

THE RECORD OF AN IMPORTANT EXPERIMENT.

ISEE in the A B C book that A. I. Root believes that brood can be reared only when the bees have access to pollen. Also in the "Manual of the Apiary," Prof. Cook is very positive regarding such being the case. As something relative to the matter has lately come under my observation, I will give it to the readers of GLEANINGS.

Last fall I prepared one of my colonies of bees on the "improved plan for wintering," which was, to take away all the combs it contained, and give them only five frames. These five frames were selected with great care, to know that they contained *absolutely* no honey or pollen, and were placed in the hive so that packing could be placed all around them. The bees were then fed from 20 to 25 lbs. of syrup, made by pouring hot water on granulated sugar, nearly all of which the bees sealed over, as I found by examination when I fixed them for winter. The reason I took this extra precaution for their welfare was because they had a choice queen which I did not wish to lose. After packing they were left undisturbed until about the first of Feb., as I supposed it could not be otherwise than that they were wintering finely, as they had a good fly on both the 13th and 31st days of Dec. Imagine my surprise when, on Feb. 1st, as I looked at some of my bees which were out on their summer stands, to see that none were getting short of stores, I found this colony quite uneasy, and ready to fly out as soon as I raised one corner of the quilt to look for sealed stores. I thought perhaps that they were only out carrying honey into the cluster, and should have felt sure of this were it not that I detected the odor of bee diarrhoea. After this, extremely cold weather, with snow and high winds, kept me from looking at them for nearly two weeks, at which time I found they were reduced nearly one-half in number, and were in a deplorable condition, smearing the hive and themselves with excrement, while the foul odor from the hive was as bad as any I ever smelled from a diseased colony having plenty of natural stores.

I now kept watch of them daily, as I wished to save the queen if possible, when, upon Feb. 24th, I saw that they could not hold out longer, as all the bees were dead but about 200. These I took into the shop, caught the queen and caged her, when I shook the poor daubed bees in the snow, where they died in a few seconds in the zero air. Don't say this was cruel; for had I served the whole colony the same on Feb. 1st it would have saved them much of misery.

The caged queen I slipped, cage and all (cage was provisioned with the Good candy), under a Hill device, which was filled with bees in a strong colony, where she remains yet. Whether she is dead or alive, I do not know, as the weather has been so cold for the past three months that no handling of bees outdoors could be done. An examination of the combs revealed about 5 lbs. of stores still remaining, and brood in one frame, about the size of a silver dollar. By a careful examination of the dead bees on the bottom of the hive I judge that about 200 bees had lately hatched, for there were about that number of white fuzzy-looking fellows there. The brood in the comb was mostly sealed, with two bees just gnawing out of the cells, one being half of its length out of the cell. This brood was dead; for when the cluster got small they left the brood and moved to the sealed stores. I had always supposed that honey had enough nitrogenous substance in it so the bees could rear brood from it in absence of pollen, but thought otherwise of sugar syrup. But from this experiment it seems that brood can be produced where only sugar syrup is used for food. The death of this colony by diarrhoea also proves that pollen oftentimes is no factor in the cause of our wintering troubles, or, at least,

that bees can have the diarrhœa in its worst form where no pollen is present in the hive.

Last fall, when preparing my bees for winter, I noted the exact condition of each colony on a piece of honey-section, which note told how much honey and pollen each had, and how much sugar syrup they were fed, as all but ten were fed from 3 to 25 pounds. This piece was secured to the hive it belonged to, so that next May, or at this time as for that matter, I can tell, without guessing, just what the condition of each colony was 6 months before. By this means I expect to gain some knowledge regarding how best to prepare bees for winter after this, the most severe winter for many years, has passed away. 16—G. M. DOOLITTLE, 49—80.

Borodino, N. Y.

P. S.—16 years at bee-keeping; 49 colonies spring 1884; 80, fall of 1884, is the interpretation of above figures.

Thanks, friend D., for the report of your experiment. I know bees will do a little something at brood-rearing without pollen; but they have always seemed to me to act as if it were like scraping the bottom of the flour-barrel, when the pollen was all gone in the hive, and they could not get out to gather any more; that is, they seemed to scrape up enough material of that nature to go a little way, but they also seemed to suffer when being made to do it, just as yours did, although I never knew dysentery where their stores were entirely of sugar syrup. You say you took away all their *combs*, and gave them only five *frames*. We suppose these frames contained empty combs, although you do not say so. If it were a less careful observer than yourself, friend D., I should suppose there was a little pollen to be scraped up in these five empty combs. Twenty or twenty-five pounds of syrup should have been ample for good wintering, but I should like to know how late it was when this quantity of syrup was given them. Did the bees have dysentery badly enough when they flew out so as to spit the snow? and if so, did those spots have that dark reddish *pollen* color which we are so familiar with?

MORAL PATENTS.

FRIEND EWING GIVES US SOME THOUGHTS ON THE SUBJECT.

THE number of applications for "moral patents" that are being filed with GLEANINGS bids fair to rival the applications for legal patents at the Washington office. The title to these special privileges would be more expressive if changed to "sentimental" patents. The best morals of the community in all civilized nations are backed up by strong supporting laws behind them. The claimants of "moral patents" for Mr. Heddon's bee-fixtures are asserting their rights of prior discovery with so much assurance that it begins to look as if he would have to "step down and out" while somebody else steps up and in.

Some one has thought of or seen a cover, case, or honey-board like those Mr. Heddon has perfected and brought before the public, and perhaps has made a model and sent it to the publisher of a bee-paper to examine and report upon. The publisher noticed its reception, and placed it in his museum

of curiosities of the same class, and that is the last heard of it. This miscellaneous species of discovery benefits no one. Suppose Mr. Langstroth, Mr. Heddon, or any other prominent bee-keepers, had done no more than this toward placing their systems and fixtures before the public, of what advantage would they have been to bee-keepers, and what *moral* right would they have had to claim those discoveries, and the benefit from them, if, in after years, other parties in their search for improving the system had hit on the same plans, and, working out the ideas, developed a system of management, and by persistent effort introduced its many advantages to the world? These are the world's benefactors, and are entitled to any advantages accruing from their labors, and not the parties who have conceived something similar at some previous period and dropped it, no more to be named or used by them. A claim to royalty might with the same propriety be made on all bee-keepers who use a revolving window in their honey-houses, as on a reversible frame hinged at the middle.

The manufacture of bee-keepers' supplies has become quite a business throughout the country, and many parties who keep no bees, and care nothing for the industry, but having mills with wood-working machines, have, at trifling expense, fitted some part of it for manufacturing supplies. The fixtures most suitable before the public are appropriated by them, and run off, much of it shoddy work. They care not a rush who invented them. If they find the articles not covered by patents, they go ahead and manufacture, giving no thought or care for the *moral* right any other person may claim.

Government has enacted laws for the protection and encouragement of those who make and apply valuable discoveries in the mechanical arts, well knowing that the moral right is a rope of sand. When inventors of improvements in bee-keepers' fixtures patent their discoveries, and follow the old system of exclusiveness, the brotherhood are apt to let them severely alone. The bee-journals publish their advertisements, and remain silent about their peculiar merits. Few know any thing about them, few purchase them, and they fall virtually still-born. But suppose, in place of the "moral" patentee requesting supply-dealers not to manufacture his inventions, while he gives the privilege to all who make supplies for their own use, he procures a legal patent on his discoveries, and accords similar privileges to individuals. The bee-journals would admit his articles in commendation of his system as freely as they do those which are shorn of all legal safeguards, and for a similar reason. Their readers are given the privilege of making use of them free from various exactions. Supply-dealers who care little for the moral right would keep hands off, and the number who make their own supplies being comparatively few, the inventor would reap the reward of his labors.

FILTERS FOR CISTERNS.

The brick-wall filter mentioned in GLEANINGS is better than no filter, but a very imperfect affair. It will keep back the coarse dirt, but let through the fine. I have tried them. E. E. EWING.

Rowlandsville, Md.

Friend E., I know there are difficulties in the way of the *moral*-patent business. There are also many and great difficulties in the *legal*-patent business; but I think, too, there are very good things about both. Shall we

not try to avoid the evils of each, and hold fast to that which is good in both? I never intended to encourage the idea that we can dispense entirely with legal patents. Where a man has worked hard for a long while on some special idea, and has developed a new field of industry, I think it no more than fair that the government should give him a monopoly of this industry; that is, so far as he by rights is entitled to it. The trouble is with those who want large pay for a very little work, and I do not know but this is the great trouble in this world.

Friend E. strikes upon one point I wish to notice. Many bee-keepers have windows that turn over on simple pivots; in fact, they have many times spoken of them in our bee-journals. Now, where a man suggests that your bee-hive frame should be reversible in the same way, it hardly seems to me as if he ought to think of calling it an invention. I doubt whether our patent-laws would recognize such a thing as an invention; and while we are about it, has any one of us, *all by himself*, worked out a very great result in bee culture? I mean, since Father Langstroth gave us the movable-frame hive, and the Germans gave us the extractor and comb foundation; and in view of the facts that have been recently brought to light in regard to many of these inventions, shall we not be a little modest about saying, "Here, friend —, that is all mine, and I want you to let it entirely alone"?—I have for some time thought that the brick-wall filters were not quite equal to the filters made with powdered charcoal, or perhaps other disinfecting substances; but they are so good a thing I believe I would have them any way, and then have a better filter besides, if I wanted it.

Where a man invents something which he manufactures and keeps constantly before the people, I think it is a very good idea for him to have a legal patent on it if he chooses; but the traffic in patents that the real inventor does not care enough about, or pleads he has not the capital to manufacture himself, is, it seems to me, the curse of the system. If a man has invented something good, let him manufacture it, and place it before the people, and develop it, getting a patent, if he chooses, to keep others from interference.

HIVE-COVERS AND OUTDOOR FEEDING.

OUR FRIEND C. C. MILLER GIVES US HIS OPINIONS AND EXPERIENCES.

WITH only a few colonies, the weight of a hive-cover is a small matter. When, however, it comes to lifting off and on fifty or more covers daily it gets to be a serious matter—a matter of backache; and the covers I have lately made, I have had made as light as possible, 4 lbs. each. They are covered with white oil cloth, and have stood very well for two seasons. Perhaps after two seasons they will need re-covering. I have never succeeded in making a cover of matched boards water-tight, with any amount of paint, so these oil-cloth covers are a comfort to me

in that direction. Their lightness, however, didn't seem so nice when one very stormy day I was kept busy a good share of the day in picking up covers and cloths blown off by the wind.

In our discussion of Heddon's covers, what appears to me a serious objection has not been mentioned. If I remember rightly he has stated that he keeps a 15-lb. stone on each cover, so of course they don't blow away. I would rather, however, have a 15-lb. cover; and as I have already intimated, that's a thing I can't stand. If some cheap device would hold the cover tightly in place, taking little or no time to fasten and unfasten, I think I should like the Heddon cover, especially for covering any thing like the Heddon supers.

OUTDOOR FEEDING.

For the last two years I have fed pretty largely in the spring, up to the time fruit-blossoms came. I used best granulated sugar, making a thick syrup, to be thinned as used. After trying the use of a lamp to keep the feed warm, I discarded it for what I thought a better way. I used for feed-dishes, dripping-pans and milk-pans, and finally had some square milk-pans made, about a foot square and 4 inches deep, made slightly flaring. For floats I used this: Take a thin board which will just fit loosely in the bottom of the pan; let it be of $\frac{3}{4}$ thickness, or perhaps half that thickness would be better. Then take a sufficient number of strips of $\frac{3}{4}$ stuff, as long as the width of the board, and an inch or more wide; nail these on the board with wire nails about $\frac{1}{4}$ inch apart, driving the nails through the boards into the strips, of course having the board uppermost while nailing. When done, place the float in the pan, board side down, and, if rightly proportioned, it will sink into the feed just enough to have a shallow depth of feed all over the board. The strips will, of course, stand up nearly an inch out of the feed. A square piece cut out of one corner leaves a hole in which a funnel can be placed, through which to pour the feed. One of these feeders will do for every 10 or 15 colonies. As I had a good many to feed I kept the stove reservoir filled with hot water, and kept two kettles on the stove to be alternately filled with syrup. Some hot water being in the kettle, about 10 lbs. of sugar was sprinkled and stirred in. When the grains of sugar were dissolved, some of this hot syrup was put into a common watering-can, the rose being taken off, and about twice as much hot water added to the syrup. Then, throughout the day, as often as a feed-pan became partly emptied, the hot syrup was poured into it through the funnel, thus going under the float, and warming up the cooler feed in the dish. If the funnel was not used, many bees were scalded. One thing that surprised me was, that, the best I could do, the bees never carried in an average per colony of half a pound of sugar in any one day. Some of the colonies showed very plainly great benefit from the feeding, and these were perhaps all strong colonies in the first place, made stronger by the feeding. Others showed no benefit whatever; and is it not just possible that some of these never found the feed? Possibly these last colonies would have done better with feeding in the hive, and I am thinking somewhat of trying this spring the old-fashioned way of filling combs with syrup to put in hive, and not feed neighbors' bees.

C. C. MILLER, 200—235.

Marengo, Ill., March 9, 1885.

You have hit the difficulty on covers ex-

actly, friend M. A light cover is very desirable, but covers that blow off are not. Years ago we used to have our covers hinged, and afterward we had them held in place with hooks; but in trying to devise some other arrangement that would permit any cover to be used on any hive, or any hive used either one or two story, we finally concluded we would rather run out in the storm and put the covers on the hives once or twice a year, than to go to the great expense and bother of hinges or hooks and catches. The Van Deusen clamp is a pretty good idea, and several other similar arrangements have been before the people; but I do not believe any of them used them any great length of time. A wire, or other spring, might be made so as to snap into the hand-holes of the Simplicity hives. This would hold them in place; but when the hives were piled up close together for shipping or other purposes, these springs would be more or less of a hindrance. I did not understand that friend Heddon kept a stone on top of the hive; but such covers would, in our locality, be very much trouble indeed, by being blown off. A cover that fits down over the hive, like the Simplicity cover, and one that has no ledges for the wind to catch under, is not very apt to be blown off. The chaff-hive covers are rather worse about being blown off than the Simplicity; but it takes almost a gale to disturb either of them.—The great trouble with outdoor feeding is as you state—some colonies get a great lot of feed, and others little or none.

THE WINTERING PROBLEM IN APICULTURE.

WHAT ARE WE GOING TO DO ABOUT IT?

ILL success in wintering is the one obstacle in the way of successful apiculture. Whenever we experience a winter like the present one, when for days and weeks we mark the figures denoting temperature with a minus sign, terrible and widespread disaster is sure to visit bees, alike in apiary and forest. Long zero weather, and sound healthy bees, seem rarely in accord. Judge Romsdel, the prince of plum-growers in Michigan, blesses Providence for the curculio. He says the "little Turk" will always be kept in bounds by the wise orchardist; and in years of plenty will, or can be made, to do most wholesome thinning, more cheaply than the same can be secured in any other way. Furthermore, the little weevil will bring utterly to naught the efforts of the ignorant, idle, or careless grower of plums, and so the price of this fruit will always be at a top figure.

The winter losses in apiculture may be regarded in the same light. Intelligent care may ward off the evil, and so not only raise the price of both bees and honey, but weed out of the business such as are sure to dishonor any calling.

For years I have been persuaded that severe and long-continued cold is the chief inducing cause of bee-diarrhœa. The direct cause seems to be indigestion, and excessive retention of the feces. This being granted, as it must be, I think, by every close student of the subject, and we must conclude that kind of food is no mean element in the production of this dread malady.

Bees are natives of a warm climate; yet, like all domestic animals of wide distribution, seem well prepared to brave and endure no inconsiderable extremes of temperature. In California, the Southern States, and the warmer parts of Europe and Asia, this wintering difficulty is unknown. The same is true in warm winters at the north of our country and in Canada. Even in winters when rigorous cold comes for short periods, broken in upon by intervals of warmth, permitting the bees to fly, the bees seem to pass unscathed. Again, in Canada and our extreme Northern States, bees are often wintered by means of good cellars or other protection, even during the severest winters, with no loss. Many bee-keepers have no more fear in wintering their bees than they have in wintering their flocks and herds. All this seems, conclusively, to show that long severe cold is the great inducing cause of the dreaded bee-diarrhœa.

How can we explain this? Bees, in normal conditions, never void their feces in the hives. In warm regions they can fly so often that there is no need of such avoidance. If confined, even for long periods, in a rather mild temperature, they keep *very* quiet, their vital activity remaining at the minimum. Thus they eat *very little*, and of course the excreta is almost nothing. Several times our bees have gone from November 1st till April 10th, and consumed not more than two or three pounds of food per colony. In such cases nearly all food is assimilated, and all refuse passes off as gas and water. There is no loading of the intestines, no occasion to void excreta. This is especially true when all the food is of the carbohydrates—honey or sugar syrup. Within the past few days I have taken several bees from hives in our cellar. The bees look bright, small, and there is no appearance of disease. Upon examination I find their intestines almost empty. Only a little whitish liquid is seen. Of course such bees, in such condition, have no need to extrude excreta from their intestines.

Yet bees never hibernate in winter. They are always active, and apparently wide awake. They must preserve their animal heat. If the air surrounding the hive remains for long periods at a very low or very high temperature, the bees are irritated. Cold acts as a tonic; they move, and must eat. Too great warmth excites, and they also eat. If for any reason they eat much nitrogenous food, as pollen, the intestines become loaded with the indigestible or undigested matter, and, as in case of all animals, such excessive retention of fecal matter produces serious disease. The bees, contrary to their habits, void their hives. Even habit is broken down by the severe irritation of the distending excreta. From bees sent me by Mr. James Heddon, a few days since, which are dead of diarrhœa, I find the intestines crowded with a putrefying mass, swarming with bacteria, giving off the usual diarrhœic odor, and crowded everywhere with pollen grains. Pollen from the hive where the bees died shows pollen grains identical with those in the intestines of the bees. Severe cold induced over-feeding. Quite likely they craved the pollen as we crave our beefsteak in winter. That they ate pollen, is sure from its great abundance in the intestines. From the fact as noticed by me now for several years, that bees are more apt to be diarrhœic when they have and eat pollen, indicates, as we should suppose, that such food—albuminous—would be more provocative of mischief. Within

the past week I have examined the fecal matter in bees dead of diarrhoea, from the apiary of G. M. Doolittle, of New York State. The familiar odor, and the swarms of bacteria, were seen as before, but no pollen grains. Here there must have been albuminoids, else there would have been no bacteria. Bees get nitrogenous food from other sources than pollen, and quite likely these bees had access to such. Some of these bees sent by Mr. Doolittle had abundance of pollen grains in their intestines. This shows that pollen and diarrhoea are not constant companions.

Again, I received bees from James Heddon, victims to the cold winter, which were fed entirely on sugar syrup. In these bees we find the syrup so entirely undigested that the characteristic sugar odor and taste is very marked. I asked one of our professors, who knew nothing of the matter, to smell of some of the bees. He said, "That is sugar." Cold irritated the bees. They ate ravenously to stay its dangers, and, failing to keep up a sufficient temperature, died of indigestion. We see, then, that cold with any kind of food may induce the fatal malady. In this last case the usual odor of diarrhoea was entirely absent. Nor was there the excessive distention noted in ordinary diarrhoea. Of course, with nitrogenous food or poor honey the disease would appear sooner, and be sooner fatal.

The practical conclusions to be drawn from the above are almost self-evident. In the northern part of our country, where very severe and prolonged cold in winter is becoming the rule, the only safe way is to provide cellars where a uniform temperature of about 45° F. can be maintained irrespective of the outside temperature. Chaff boxes and winter packing may suffice for the most part, but will not prove sufficient in our coldest seasons.

Again, good food, either pure honey or pure cane-sugar syrup, is safest. Not that bees may not winter with plenty of pollen, or not that they may not die with no pollen; but from our experiments, as well as what we know of foods and the habits of bees, we can easily believe that food without nitrogenous elements is safest in winter for bees.

Of course, some colonies of bees, like some men, may possess such an excess of strength and vigor that even cold and poor food may be powerless to work evil. Yet this does not argue against the facts as stated above.

I have said nothing in this paper as to dampness or ventilation. It is presumable that a dry, pure atmosphere, is best for bees. Yet the fact that I have known bees to winter year after year in very damp cellars, with no loss, and that I once wintered bees in a snowbank, during one of the most disastrous winters, with the hives tightly sealed with propolis above, and with ice below, and never knew bees to winter better, makes me wonder if we should have to heed moisture or ventilation, in case we secured proper food and exactly the right temperature.

A. J. COOK.

Agricultural College, Mich., March 13, 1885.

Friend Cook, I like your opening remarks very much indeed. It strikes right on a point where for some time I have been thinking. Especially has it come home to me with strong conviction since my visit at the South. The point is this: The difficulties we meet in all our separate industries are in one sense blessings. Our friends in the South (who have no trouble with wintering,

no trouble with zero weather in their attempts to raise fruits and garden stuffs with all these great aids) do not by any means accomplish as much as we do here with our unseasonable zero weather. A zero temperature punishes the shiftless; but to the earnest, zealous, thoughtful, hard-working man it is a positive help. Let us, then, laugh at storms, coming even in the latter part of March, as they do now while I write; let us laugh at insect enemies, and let us thank God for all these obstacles that only serve to teach us great truths, and to have faith that they come from the loving hand of the kind Father above. You speak of a uniform temperature of about 45 degrees. I have mentioned elsewhere that the Mammoth Cave averages about 55 degrees—no difference at all, winter or summer. Is not 55 better? I can testify from experience, that it is a very comfortable temperature for working, without being encumbered with overcoats or winter covering. The temperature is not unpleasant to sit down and rest, when you are tired. I presume if we go down into old mother Earth far enough to be free from external influences we can always depend on 55 degrees; and it seems to me it is not going to be a very hard task to do this. Bats cluster in great numbers near the mouth of the cave, and stay six months without food or exercise. Very likely, though, they go in when they are in flesh, and come out spare and lean. I believe I entirely agree with the deductions you draw from the valuable experiments you have given us.

FRIEND WIGHT'S UPS AND DOWNS IN BEE CULTURE.

HOPES NOT BLASTED, THOUGH THE LOSSES HAVE BEEN MANY.

FRRIEND ROOT:—You may not care about my coming, since I have no sunshine to bring you; when, too, you have such an accumulation only awaiting their turn in "Blasted Hopes." I did not care so much about my former loss, when, under Mr. King's and Mrs. Tupper's plan, I had built up a small apiary in the old American hive, because that gave me the opportunity of changing my plans and style of hive.

Years went by, and in the fall of 1880 I had 110 colonies, mostly Italians, on the L. frame. I actually sat in my chair under an apple-tree, leaning and musing over the lines:

"How doth the little busy bee
Improve each shining hour,
In gathering honey all the day
From every opening flower!"

Neither did they nor I think of the disaster that was awaiting them. By April I had only 17 colonies left. The following year was a good one, and, by the aid of the empty combs, they increased rapidly, when, at the end of the season, I had about 40 colonies and 1600 lbs. of nice section honey. Since then I have been successful, both in surplus and in building up. Also a fine trade has been established for my honey at home. Last fall I had 140 colonies, but no surplus. I united them to about 100, fed them 3 bbls. of granulated sugar, packed them with chaff, and to-day I find 5 alive out of 40. From these I

know the fate of the others, except 15 that are in the cellar.

"Storm-king passed by their darkened door."

If these 15 should live till May flowers offer their precious cups of nectar, the children may still have honey on their bread and butter.

Shall I quit? If I do I shall not be much the loser financially, calculating from the beginning; and I think I am wiser and better from experience and after reading our wise and prudent apiarists. Their terms are almost household words; from "Harbison's sandy strain, from Perrine's floating skeps, and the dizzy heights of the tiny towns of King and Muth to"—the perfected "home of the honey-bee."

Bedford, Iowa, Feb. 28, 1885. MARCUS WIGHT.

Friend W., I should say, by no means quit. If cellar wintering turns out the best in your locality, winter in the cellar; but, have you given nicely made chaff hives a thorough trial? Yesterday morning, while waiting for the train, one of our bee-men at a neighboring town remarked that he had already lost 20 out of 40; but on further questioning he admitted they were in Simplicity hives, and he was not sure he fed them enough in the fall. Our apiarist reported Thursday, March 5, that our 198 colonies had all passed safely through the severe weather of the past eight weeks. At times the thermometer has been 18 degrees below zero, and it was below zero more or less every few days for a period of five or six weeks; but, as I told you last fall, they were put up in excellent order, and had every thing just as it should be, or as near as we knew how.

OUR FRIEND GALLUP AGAIN.

He Tells Us Something About the Great Honey Crop of 1884.

IS CALIFORNIA A GOOD PLACE FOR A MAN TO MAKE A LIVING?

THE article on page 25, Jan. No., has called out scores of letters of inquiry; and if you will allow, I will give some statements of general interest. The aggregate yield of honey in 1884 for California is about nine million pounds—enough to give every man, woman, and child in the United States a feed of California honey, and still have some left for company. A writer in one of our papers says it would load 600 freight cars, or a train nearly 5 miles in length; or, put up in a style of bottle largely used here, and placed 8 feet apart, it would reach from San Francisco around the globe, and meet again at the Golden Gate, and still there are millions of tons of this sweet not gathered, for reasons that I can not stop to enumerate now.

The most frequent question that I am asked is, "Could I, with 1000 or 1200 dollars, make a comfortable living in California?" With that amount you could purchase a bee and stock ranch combined, and already stocked with bees. I know of three places now, and two of them are within one mile of a schoolhouse, and the other is within one mile of the celebrated San Juan hot springs, where there are from 300 to 500 campers, every summer. But if you could not make a living with that amount, it would be the easiest thing out to let some sharper get it away from you, and without it you could certainly get a good living.

My oldest son has been out here on a visit from Northern Iowa this winter; and what astonished him was, that he could not find a single person that wanted to go back east to live. We tramped some ten days among the bee-keepers, and the most of them came here broken down in health, and without money, and have gained their health, and have good homes, and are perfectly satisfied with their lot. Health is worth every thing; and as near as I can learn we have the most healthful climate in the known world. While we were tramping we saw a large swarm of Italian bees with their combs, brood, and stores, all built on a bush right in the open air, and within two rods was probably the parent stock in a hollow live-oak tree. This was the 13th of February. The comb looked clean and nice. It was about 18 inches from the ground, and the sheets were about 18 inches long. The colony was a powerful strong one, and they were carrying in the pollen on all sides at a wonderful rate. We left them there undisturbed. There is no patent on that hive.

Bees are in remarkably good condition; and if we have but a small supply of spring rain which we usually have, the season must be a good one. A man can stick down a fig and grape cutting here, and then (literally) sit down under his own vine and fig-tree, and there is none to make him afraid.

I am nearly 65; came here 8 years ago, completely broken down in health; have regained my health, and am strong and vigorous, and would not hesitate to commence again with 50 dollars, or even less, and raise an orchard that would astonish an eastern man as to growth and productiveness in three years.

E. GALLUP.

Santa Ana, California.

Thank you, friend G. At the bee-keepers' congress in New Orleans there was some stir about the extravagant reports made about California, and I believe the decision was, by those who ought to know, that considerable exaggeration had crept in somehow. Those who are restless and uneasy, and want to find a better country, should always keep in mind that some people will make a living anywhere, and help others to make a living; and then, again, there are a great many who *won't* make a living anywhere, but who will hinder others a good deal. This latter class would probably only waste more money by moving to California. We are glad to rejoice with you in your great honey crop; and one of the best things about it is, that it is *beautiful* honey too.

WINTERING BEES.

OUR FRIEND DAN WHITE UTTERS SOME WORDS OF WISDOM.

THIS problem has been discussed enough to have the thing solved; but as this has been a severe winter, and bees have suffered by it, the pollen theory and every other theory will come up again. As far as I can learn about here, there has been a general cleaning-out; especially bees in single-walled hives are all or nearly all gone. I expect to hear like reports from all the Northern States. Some have lost heavily in chaff hives. I have to report a loss of 7, being the first time for me to lose a colony in a chaff hive. I

have always said they were a perfectly safe hive to winter in, no matter how cold it might be, and I now feel prepared to say, having more confidence than ever, that bees will never die wintering in a chaff hive, if the bee-keeper will do his part. It will not do to leave or neglect any part of the preparing for the winter campaign. It may be natural to judge others by one's self, so I will tell you some of my thoughts when preparing bees for winter.

I find it takes time, and is somewhat laborious, to do the thing right; and as I go along and come to a hive not recently handled, combs somewhat fastened together, bees cross, etc., I say to myself, "Last winter was so cold that this winter will be easy, and will let you go just as you are, by merely putting in the chaff cushion." So I go on, missing every once in a while one in this way. I know by actual experience this will not do. How many bee-keepers are there who never handle the brood-frames, and, especially in the fall, fix them the easiest and quickest possible way, or let them go without doing any thing? I knew of several who have invested in chaff hives, and have done so contrary to my advice. I well know they would expect the hive to do it all. Well, this spring finds them with the hives minus any bees. So it goes about here, and is it not so elsewhere?

I last fall experimented with four colonies in chaff hives, giving stores composed entirely of honey-dew, or "bug-juice," as some call it. Every bee in those hives was dead three weeks ago; the three other dead ones were left on the guess-so principle, then I have probably 15 that will need good diligent nursing to make them what they should be by the time honey comes.

I find in every instance, where I last fall did my duty, all is well. In short, my bees have suffered just in proportion to my carelessness.

I told you about the easy winter I had in my mind. Well, to save the expense of 13 chaff hives, and fixing the weather all right, I started in with 13 colonies in Simplicity hives. I used two division-boards in each, a good warm cushion in the top hive, fixed ventilators also, and took pains to give nice stores; but all to no purpose, as nine are dead, with fair prospects of losing the other four. Ten days the last of February, with mercury every night from 6 to 16° below zero, and scarcely above zero any day during the time, is when these bees ceased breathing. Now, after this I promise myself to every fall prepare my bees for waves of this kind; for bees on summer stands, unless protected, can not stand such weather.

I will close this now, as this morning, at 6 A.M., March 17, mercury stood exactly at zero, and a later report may not look as well as the one I have given. I have 105 chaff hives with bees in now.

New London, O.

DAN WHITE.

Well done, friend Dan. Such letters as yours are hopeful, and I am sure you are right. Your remarks need to be placed alongside of Prof. Cook's, in another column. It is not so much that we want more light or more ventilation in regard to this subject of wintering, as it is that we live up to the light we have already, and to act up to our own convictions. This 20th day of March the thermometer is 4 degrees below zero, and last evening it was 8 below. Now, then, we want to go to work every winter with the

expectation of having the weather possibly 8 or 10 degrees below zero as late as the first of April. Let stores, chaff packing, and quantity of bees, be sufficient for just such a contingency. When the weather "lets up" a little, we will tell you how our chaff hives have stood this last blizzard.

A REPORT ENCOURAGING AND DISCOURAGING BOTH IN ONE LETTER.

WHAT SHALL WE DO WITH BEE-HIVE THIEVES?

I COMMENCED last spring with 4 hives; increased to 18 by natural swarming. The season was not good for honey; the spring was wet and cold; and when white clover came there was no honey in it. Basswood very little, and then the latter part of the season was so dry it seemed as though every thing must dry up. However, I got nearly 400 lbs. of comb in 1 lb. sections, and all went into winter quarters with full supplies save three. Two I took up, as they were drone-layers. The third one went to supply some one who does not live up to the golden rule. Talk about being liberal, as some do in GLEANINGS, as an antidote for thieving, may do in some cases; but kindness and liberality are worse than thrown away on some. Some talk of setting guns. Well, this is wholesome argument for some; but before I would resort to that I would do as one of my neighbors did; viz., go out of the business.

I have always given freely to all in reach of me, and have sent to them when not asked for; but as I said before, kindness and liberality are only thrown away on some people. They took this hive from me, a Simplicity upper story full. Had they been content with surplus contents, and left my poor bees alone, I do not think I should be writing of it now; but after taking all the contents out they piled the hives up and burned all, a large swarm, and a valuable Italian queen, and that within a stone's cast of my house. If they keep up their wanton destruction, you will have one customer less, and they be compelled to forage somewhere else.

How the bees are coming out this spring, is hard to say as yet. Some have lost heavily; some more or less. I have 8 in cellar and 7 out under the snow, totally out of sight. Those in cellar are all right, and I have no fear for those under the snow.

I took not a little pains last year, by inquiring of those who lost heavily, and found that an average of 7 black to one Italian was the result. I should like to know how it is in this respect in other parts, where they lose so heavily by reason of the cold.

Did you ever know a swarm to leave after filling their hive most full? A neighbor of mine tells me he had one, after being lived ten days, leave pell-mell for the woods.

CLIPPING QUEENS' WINGS.

Take a small bush, sharpen the stub end, stick close to the bottom-board, but leaning from the hive; and when the swarm issues, the queen, being unable to fly, will run up the bush on the return of the swarm. They will cluster around their queen, you can just pull up the bush and carry all to the hive, and the work is done.

H. L. BOSS.

Caro, Mich., March 16, 1885.

Friend B., you did wonderfully in increasing four hives to eighteen by natural swarm-

ing, and getting 400 lbs. of honey. Your locality is certainly a good one, and I guess you are a good hand to take advantage of it. —In regard to thieving, which you think can not be helped by kindness or any thing else, did you never hear of a promise that, if we do not weary in well doing, we shall in the end come out victorious? I am not sure that I have very much faith in giving honey or any thing else to bad people in order to make them good. Sometimes you can invest honey and money in that way to good advantage, and I would by no means overlook such ways of working to restrain sin. Please do not accuse me of harping on the same old story when I say, that the description you have given of your locality indicates most clearly that you have a class of people that need educating and Christianizing. Have you plenty of schools, and are all the children obliged to attend at least part of the time, whether they will or not? Have you churches and Sunday-schools in your vicinity? and have you Christian workers who are working steadily and faithfully, going over the whole ground completely, to see that all children who do not go to Sunday-school are visited, and not only that, but that their parents as well are labored with? It seems to me there must be a gang in your vicinity who are preparing themselves for the penitentiary, and who, perhaps, have for some time held themselves so much aloof from Christian people and Christian influences that they hardly know that such things exist. The responsibility lies upon us all; we *are* our brother's keepers; and if we evade and shirk these responsibilities, sooner or later God will punish us in just the way you have pictured out. It was this same kind of evasion of responsibilities that brought the children of Israel into captivity in olden times, and the same thing kept them there. Shall we consent to be captives, and let this spirit of evil congratulate itself that it has driven us from the field of bee-keeping, and other like industries?—Your idea of a bush in front of the hive is tiptop, friend B., and I think the suggestion is a new one. Will some of the friends try it and report?

MANUFACTURED HONEY.

IS THE WHOLE WORLD A FRAUD AND A CHEAT?

INCLOSE you an article, headed "Manufactured Honey," copied from the *Philadelphia Times*, which I should like to have you notice, and make some comments upon. Is there any such process for manufacturing comb honey? I should think that a little more than human skill could accomplish.

S. AMBROSE.

Ash Ridge, Wis., March 2, 1885.

Friend A., there is no process for manufacturing comb honey, and the *Philadelphia Times* people ought to be ashamed of themselves for publishing such disgraceful foolishness. My opinion is, that the whole thing is gotten up by some reporter, to make a sensation. I do not believe any *bona-fide* dealer ever told any such stuff. We give the article in question below:

The adulteration of food has been practiced to such an extent that purchasers no longer expect to get a pure article, even when paying the highest prices. It is generally supposed that two-thirds of the milk sold in all our large cities is deprived of half its cream; it is known that butter is made from beef fat and cotton-seed oil; maple syrups have lately been made from almost any thing of a sweet nature, and now it is stated that most of the honey we eat is manufactured, and that much of it has not even a drop of genuine honey about it. This alleged honey was first sold in this city some five or six years ago. Its sale at first was scant, but for the past two years it has become very popular, and it is claimed that there is now little else to be found in the market. Some of it is sold as manufactured honey, though a great deal of it is dealt out to the unsuspecting purchasers as the natural product of the honey-bee.

The spurious kind is usually put up in little square boxes, which sell for from twenty to thirty cents a pound. It looks like honey, and it is said that it takes an excellent judge to tell that it is a fraud on the bee. The comb is manufactured with such skill that but few can tell it from the genuine article. It is made from paraffine or beeswax, and the honey is blown into it by machinery. Another kind is put up in glass vessels like ordinary jelly-packages, the center of which contains a piece of honey-comb, and the honey is made by pouring about six parts of glucose around one part of honey in the comb. Some of it is adulterated with glucose, some with cane sugar, others by heating ordinary sugar with an acid; but it all resembles honey, and to a certain extent has its flavor and odor.

"Of course, it is not so good as genuine honey," said a dealer, when questioned about it, "but it is cheaper, and the parents prefer it and the children cry for it. I sell a great deal of it, but my customers all know what they are buying. Yes, it is a fact that many prefer butterine, made from pure fat, to much of the country butter brought to market. They seem to think they know what the butterine is manufactured from, while they have their doubts about the manner of adulterating country butter. I suppose they think the same way about honey." Further inquiries revealed the fact that manufactured honey is sold extensively in the city, and especially in neighborhoods where the poorer classes reside. In some places it is temptingly displayed, and the dealers push it on account of the large profit in it. In most instances, however, it is sold as manufactured honey.

Some dealers decline to sell the spurious kind, although they admit that there is a large profit in it, and that it is becoming very popular. An up-town groceryman who refuses to handle it, says it is poisonous, and predicts some startling results from its use. On the other hand, it is claimed that it is not as dangerous as genuine honey. A dealer in the adulterated kind, who displayed his knowledge of both chemistry and history, says that it is a well-known fact that sometimes poisonous qualities are taken from the flowers by bees, and find their way into honey, which has been known to produce dizziness and sickness. He referred to the fact that soldiers of Cyrus once met with a honey of this kind, and that it came near destroying the entire army.

The color and odor of genuine honey are due to the character of the flowers from which it is taken. It is said that the Vermont honey is as clear as pure water. This honey, which is celebrated all over the country, is taken from white clover. A delicious honey is also taken from the orange-groves of California, but this has been so successfully counterfeited that it is now difficult to tell the bogus from the genuine. Wherever bees feed upon buckwheat they produce excellent honey, it matters not what climate it may be in. Some of the best honey sold in the Philadelphia market comes from Chester County, while that from Lancaster is also excellent. But the spurious kind sells more readily, presumably on the ground of economy.

The originator of the above string of outrageous falsehoods ought to be hunted out, and held up before the world. In regard to the report of the California honey being adulterated, we copy the following from the *American Bee-Journal* of March 18:

"Some outcry has been raised in England about 'glucose California honey,' which is not only base-

less, but senseless. The proof of this is, that the article of glucose laid down in California is worth quite as much as the honey itself. Therefore, add to this cost the additional expense of tanking, mixing, the cost of new packages which would be required, all told, say 2½ cents per pound, it makes a total cost of, say 6½ cents, when the pure honey itself can be bought at 4½ cents.

It seems to me as if the spirit of the evil one himself were running rife among the newspapers, in their efforts to make out that everybody but themselves is all the while up to some sort of trickery and fraud. The article quoted from the *Philadelphia Times* above says: "It is generally supposed that two-thirds of the milk sold in our large cities," etc., and that "most of the honey we eat is manufactured;" "not even a drop of genuine honey about it." Well, my opinion is that the people who affirm such falsehood and villainy as the above, generally judge their fellow-men by the blackness existing in their own evil hearts. Because they would adulterate and steal whenever an opportunity of any sort offered, they think the world are all just like them.

In this connection I feel moved to mention something I once thought I never should mention. At the bee-keepers' congress in New Orleans, a man we all know so well by name, C. O. Perrine, wanted to speak. Well, although I did know something of the man's past character, I did not know, and it did not even occur to me, that we had a man in our broad land who had the unblushing effrontery to get up before an intelligent audience, and brag of the way in which he had told lies, and swindled the people of America. He told about how he had put up sugar syrup, and sold it through Cincinnati and other cities, labeling it "Pure Honey," and then boasted, too, that when glucose came into market he sold stuff in glass jars, consisting of from 50 to 70 per cent glucose, labeled it "Pure Honey," and put his name on the label. He did all this without even a trace of color on his face to indicate that such a thing as shame could find a lodging-place in his vile heart. He closed up by saying he was out of the business. No wonder; and I felt almost sorry he could stand there before a group of intelligent and honest men, letting them know that he was, contrary to his just deserts, outside of the penitentiary walls. I have heretofore taken Perrine's part somewhat, for I could not believe the stories that were told about him; but he stood up there and seemed to enjoy telling worse things of himself than anybody had ever told about him. In closing up he did not even claim that he had left off his wicked practices, or proposed to do so. He had simply gone into other business. Is it any wonder that people are suspicious, and somewhat ready to credit these newspaper stories, when things like this come to light? When you want to buy honey, or any thing else, be sure that a good man's name is on the label. Thank God, we have plenty of good men left—men who will live and die honest.

It was some years ago that Perrine was in this wholesale business of adulterating honey; but even at the high price of honey and the low price of glucose, it seems he did not make money, and I should suppose that pres-

ent pay was all that such a man ever thinks of. I do not know of anybody now who makes a business of adulterating honey. The Thurburs put a piece of comb honey in a glass jar, pouring a fine article of glucose around it; but a label is put on, explaining that this surrounding liquid is "corn syrup." I am sorry to say, however, that the "corn syrup" label is not as conspicuous as it might be. I do not believe any man ever fails in business because he has been too honest. The lives of our successful men will bear me out in this, as everybody will admit.

BEE - KEEPERS' CONGRESS AT NEW ORLEANS.

Continued from Last Number.

LATE in the afternoon of the 25th we came to the end of our long journey, and stepped from the cars to the platform, in the city of New Orleans. On our left lay the veritable steamers with their heaps of cotton bales, and on our right was broad Canal Street, running up into the city. Ernest and I felt for a time like a couple of strange "cats" in an enormous "garret." Zero weather and the snow-clad fields were gone in very truth, and yet I could not make it seem possible that the weather had not changed, and that our folks were having green grass and sunshine away up in Ohio. There was no time to waste. It was in the afternoon of the second day of the bee-keepers' congress, and so we hunted up a lodging-place that had been recommended to us; and as soon as we had deposited our cumbersome overcoats and other useless traps, we jumped on a street-car for the Exposition grounds. These street-cars were literally chasing each other all the while between the city and the grounds. It is a good thing they are, too, for it is very convenient indeed to be able to find plenty of room to sit down and look out of the windows at your ease. Pretty soon my eye caught a sight of the watched-for orange-trees, laden with fruit, and many were the exclamations of surprise. The people seemed very pleasant and sociable. They had doubtless become fully accustomed to the expressions of the Northerners. Our bee-keepers' badges once or twice called forth some expressions of curiosity, but they did us good service in helping us to recognize bee-men when we passed them. Every thing seemed to me so much like the Centennial of 1876 that it does not seem as if it would be worth while for me to attempt to describe it all. It is pretty much like the expositions we have now in all our large cities, only, as a matter of course, it is on a more extended scale than the world has ever seen before.

The grounds and the greenhouse were special attractions to me, but Ernest did not care so much for them. In the way of manufactures, one can see almost every thing going there that is to be witnessed on the face of the earth. Exotic plants, and plants from every part of the tropics, and from almost every part of the world, were to be found growing there outdoors, or in

the greenhouses. But the things are brought together more for curiosity than to demonstrate what can be done in the way of improved agriculture. It seems to me they ought to have employed Peter Henderson to show them what could be done in the way of market gardening in such a climate and such a soil. Although almost all kinds of garden vegetables could be raised outdoors without any trouble, I did not see any, either on the grounds or in the city, that I thought were really extra. The productions of improved agriculture from the different parts of the Union, and from different parts of the world, were collected in the Government buildings, but I had some way got it into my head that I should see things growing, and improved agricultural machinery there in actual use, but I did not find it. Beautiful cultivators, seed-sowers, sulky plows, and the like, were on exhibition from every part of the world, but none of them were actually at work in that beautiful soil; but may be they will get to it after a while. Some beautiful beds of flowers were in bloom on the grounds, and collections of bulbs were especially attractive; but there was too much of an air about them as if they were taking care of themselves. Dr. Besse's apiary looked a little that way. There were 50 or 100 hives of bees scattered over a nice plat of ground; but the biggest part of the hives were unpainted, and those had evidently been in use several years. I suppose the doctor was pretty busily occupied in the buildings most of the time.

Notwithstanding the lack of these few things I have mentioned, the Exposition at New Orleans is all that has ever been claimed for it, and more too; and the complaints that have been made in regard to some of the minor features, I think are unjust and undeserved. We found nothing lacking in the way of entertainment while in the city. People were kind, courteous, and obliging; and if there was any drunkenness I did not see it. In fact, I saw more of Satan's work in walking the length of one street in Cincinnati than I saw during my whole trip of over a week through the Southern States.

When we first went on the grounds we were greatly tempted to loiter about and see things, but we knew our first duty was to report at the bee-keepers' congress. We entered the hall while somebody was speaking; but as soon as he finished, our stalwart friend Muth rose up and made a motion that we have a recess of fifteen minutes, so that everybody would have a chance to shake hands and get acquainted with "Brother Root." Friend Muth always gives my name the long sound—that is, speaking the *oo* as it is in *boot*. Didn't they hurt my hand, though? I pretty soon felt afraid to see some of those good-natured, big, tall, Southern friends making their way toward me. Many and many times did I hear about the Home Papers, after getting a little acquainted. One man said that he had a neighbor who had been led to the Savior by those Home Papers, and this neighbor commissioned him to take especial pains to see me and tell me the debt he owed. Three or four days is altogether too short a time to take any sort of a view of

such an immense field for instruction as the Exposition, to say nothing of having time for friendly talks with such a multitude of friends who knew me perfectly well through my writings, but of whom I knew comparatively nothing. Since coming home, in getting hold of these letters from the friends, one after another, a feeling of sadness comes over me that I did not have an opportunity of having a longer talk, or of saying something, even if nothing more than "How do you do?" or "Good-by;" and the biggest part of the time, the latter was not said at all.

Dear friends, I do not know how I can well tell you much more of that great event of my life, my visit to New Orleans; but in our next number I want to take a little space to tell the juveniles something about the Mammoth Cave, which I visited on my way home.

MRS. HARRISON PAYS A WORD OF TRIBUTE TO A GOOD MAN.

OBITUARY NOTICE OF THE DEATH OF WM. WILLIAMSON.

ONE of the pleasantest anticipations, relative to the bee-keepers' congress, was that of meeting friends and acquaintances made at former gatherings of its kind. In corresponding with Dr. Brown, he informed me that Mr. and Mrs. Williamson would start for New Orleans Feb. 13, and remain there until after the bee-keepers' meeting. On arriving at the Windsor, my first inquiry was whether Mr. and Mrs. Williamson were stopping there, and I was informed that he had been called to a higher tribunal.

On arriving at Lexington, Ky., in the fall of 1881, to attend the National Convention, I was informed that I was expected to be a guest of Mr. Williamson's, at which place he lived, and that a place had been reserved for me. The Williamson brothers resided in a double dwelling; and one of the families being absent, both houses were appropriated for the use of guests, and a large number gathered around their hospitable board, and met together in their genial parlors. "It was good to be there;" and when the bus was filling with departing guests, and the driver called out "all aboard," some one would jump from it, and go through with another handshaking, as if reluctant to depart.

When the National Convention had adjourned, Mr. Williamson procured a conveyance and took a remaining party to visit Ashland, the home of Henry Clay, Kentucky's great statesman; from there to see the horse palace of General Withers, and its celebrated trotters. In the gloaming we gathered around the monument and grave of Henry Clay, and also cast a sad look on the little mound, erected over all that remains of the famous rider, John Morgan.

The pleasant hours spent with Mr. Williamson's family are emblazoned upon the tablet of memory never to be effaced. Now the home is in mourning, the wife a widow, and the children fatherless. On my own behalf, and of those who gathered there, I extend to them my sympathy in their great bereavement. May the God of the fatherless and of the widow sustain them in their affliction.

Peoria, Ill.

MRS. L. HARRISON.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

WHAT ARE THE NEW HONEY-BOARDS FOR?

YOU said in your report of the Mich. State Convention, that you had never before fully decided in your own mind what the honey-board was for. Will you or some correspondent please tell me what it is for in making comb honey, as I have not yet found out to my satisfaction?

A. S. VAIL.

Michigan City, Ind., Feb. 18, 1885.

Why, friend V., bless your heart, didn't I say the honey-board was for the express purpose of preventing the bees from waxing the sections and section-case fast to the frames, and for no other purpose that I could tell? The Hutchinson honey-board "strains out the drones;" but Heddon's is only that we may have things loose when we want to pick them up. It is a little queer, that neither friends Heddon nor Hutchinson told just why they *did* want a honey-board until after it had been talked about for some time.

SAD NEWS FROM OUR NEIGHBOR VIALLOU.

On my return home Saturday morning I found every thing working nicely; but at 11 o'clock at night I was awakened to see my factory on fire; and before any help could be given, the whole was blazing furiously, and the next morning there were but ashes and melted iron, etc., left. It is a total loss of over 3000 dollars, having no insurance—our insurance companies declining to insure saw-mills. I will rebuild at once, but it will be at least three weeks before I can fill orders, as I intend to build a frame building so as to be at work as soon as possible.

P. L. VIALLOU.

Bayou Goula, La., March 2, 1885.

Well, friend V., if you were unable to get insured, it is a rather sad affair, certainly. I presume you would, of course, have no trouble in effecting insurance if you had a brick building. Very likely another wooden building will be the thing for you to start up with this season, but I would assuredly start about it as soon as the rush is over, getting my machinery in some sort of a building that can be insured, and then I would have it insured, or stop business. Of course, one may do his own insuring when he has the means at hand to rebuild as fast as he burns down; and where the insurance companies charge excessive rates this might be the best thing to do, where one has this extra capital. As a rule, however, it is a pretty hard matter to start in business again without any insurance; or, at least, it greatly cripples one to be obliged to do so. In your warm climate it seems to me your building might be covered with sheet iron, which is not very expensive, and is almost fireproof. Of course, if you have very much bee-hive material stored in your factory, that of itself might ruin the building if it got afire. To avoid this, I would have a warehouse far enough away so that it might burn without endangering the factory, and then have a suitable track and car to run the stuff back and forth. That is the plan we adopt here.

If you are located close by the railroad, the whole thing can be managed without very much additional labor in handling. One thing is certain: Supply-dealers can not afford to burn up very many times without insurance.—As the above letter is dated March 2, we presume friend Viallou is ready to fill orders by this time as usual. I would hope that the friends, in making out their orders, will remember that the best way in the world to show one's sympathy for a suffering brother is to give him a little lift in the way of patronage and the like.

A REPORT IN REGARD TO FRIEND KALER'S CARP-POND, ETC.

Nearly five years ago I started into the bee-business with one colony of Italian bees which I obtained from Chas. Dadant & Sons, and in October last I put up 66 stands in chaff hives on summer stands. Last fall I built a fish-pond which is about 140 feet wide by 165 feet long, and an average depth of 6 feet. I bought 211 German carp of W. S. Kaler, Andersonville, Ind., and stocked my pond. I have seen Mr. K.'s pond, and it is a success without a doubt. I see no reason why every farmer can not have a pond and raise his own fish. J. W. SMITH.

Rock Lane, Ind., Feb. 16, 1885.

FEEDING BEES ON THE GOOD CANDY.

The method of using granulated honey on top of the frames, to feed bees, as suggested by friend Fradenburg, I believe, will not work well if the colony is small, or the quantity given at one time large, or the weather very cold, as bad results will certainly follow, and loss result. A better and perfectly safe way is to take a piece of burlap or old sacking, say a foot or ten inches square, and put one, two, or three pounds of the granulated honey on it, then fold over one part of it, covering the honey completely, and flatten it down, then place right over on the frames, then cover up snug and warm. The bees will take the more liquid part through the cloth, and then will cut through and remove the other, which greatly resembles a good article of brown sugar. This is an excellent way to feed for spring stimulating. Try it, friends.

FLANAGAN & ILLINKI.

Belleville, Ill., March 14, 1885.

Thanks, friends F. & I.; but while reading it, it occurs to me that Langstroth describes exactly the same food, and advises wrapping it in a cloth. See page 274, "Hive and Honey-Bee."

MY FIRST WINTER WITH BEES.

I have had a desire, from a boy, to work with bees, but never had a chance until last spring (1884), when I bought three colonies and one of your A B C books. The bees commenced the summer in good shape, but I got too anxious, and increased them to 9 by artificial swarming; and the summer being a very poor honey season I got no honey, and had to feed syrup for them to winter on. They wintered very well up to between the 15th and 20th of Feb., when the mercury ran down to 20 and 22 degrees below zero, and killed all my new swarms, leaving me the three I started with in the spring. My experience is rather discouraging, but I have learned that it is all-important to commence the winter with good strong colonies. I have bought 5 more

colonies, part Italians and part hybrids, all in good condition; have moved them home, and now have 8 strong colonies. If I get forgiveness for past mistakes I will try to manage my bees better in the future.

I quit the use of tobacco the 15th of last July, after using the weed for 3 years. I was riding in the smoking-car of a railway train near Cincinnati, and the resolution seemed to come to me all at once, and I took a plug of tobacco out of my pocket, and a cigar out of my mouth, and threw them out at the window, and have "stayed quit" ever since. Although having a natural appetite for tobacco, by the help of God I am and wish to remain a total abstainer. I prize your Home Papers very highly.

Winchester, Ohio.

T. L. REES.

Friend R., your resolutions, both in regard to bee culture and tobacco, have the right ring; and I tell you, when these good impulses come we want to recognize them as the voice of God, and heed them accordingly. When I can see a man take a plug of tobacco out of one pocket and a cigar out of the other, and resolutely throw them away, asking God to help him, then and there I begin to have faith in my fellow-men. May God bless and help and sustain you. If you go on in that way I know you will succeed, with bees or whatever else you set about.

EARLY QUEENS FROM CALIFORNIA.

I will introduce myself as a Maine man just arrived in this far distant bit of Uncle Sam's territory, and starting in bee culture. I have invested in about 100 stands, ranging from pure Italians to blacks. The season here promises to be dry—no rain since Jan. 1—and I have started nuclei preparatory to Italianizing, and I write to ask if you can use the superseded queens, as I note in your catalogue you supply such when obtainable. I can send them any time, as I now have queens laying that I have raised since coming here in November. If you can not use them, do you think it would be advisable to advertise them? I wish to sell them if possible, as a poor season means that every cent must count, to a new comer at least. I learned my "trade" of J. B. Mason, Mechanic Falls, Me., being there a part of two seasons. If I succeed in raising pure queens after a while, as is my object, do you think you would want a few early ones next season? Both black and white sage grow in my apiary in abundance, and we are picking strawberries, and have been for some time.

G. B. WOODBERRY.

Verdugo, Los Angeles Co., Cal., Mar. 9, 1885.

Friend W., we do not buy hybrid and black queens, because there is not enough money in them to pay the expense of two shipments. Those we offer for sale are such as are found in our own apiary, having a trace of black blood. Shipping queens from California to the States is too risky, and I would not advise it. I will tell you what you can do, however. Keep a good supply of all kinds of queens constantly on hand to supply the demand from your coast. No one has ever done that, that I am aware of, and it makes me feel bad to see orders coming to us from away across the Rocky Mountains. You can get them through, it is true; but it is poor policy all round to ship queens such long distances. We expect to get our early queens from Florida and the Southern

States. You see, this is nearer home, and they won't have to take a long cold trip across the Rockies.

SOUND DOCTRINE.

Tell B. F. Pasley (p. 170) to get down on his knees, if he needs a wife, and ask our Father in heaven to give him one, and God will get him a good one. No patent applied for. Ask in faith. "The Lord keep thee in all thy ways." D. MCKENZIE.

New Orleans, La., March 11, 1885.

Friend M., your doctrine is sound and orthodox. God gave Adam his wife, and it is fair to presume he will do the same for any of us; and may I take the liberty of adding, that when the wife comes she should be regarded as a gift from God, and treated accordingly?

PURIFYING WAX.

Will you please tell me how you purify wax for foundation? My own wax, made with a wax-extractor, is all right, clean enough; but I get some from my neighbors that is very dirty. I notice considerable talk in GLEANINGS about the Heddon hive and system. Let me say, the Heddon fixtures throughout are perfection, in my opinion. I have discarded ever thing else for them. It cost me considerable to make the change, but I am not sorry. Bro. Heddon deserves much credit for his inventions.

E. J. SCOTFIELD, 4C-100.

Hanover, Wis., March 10, 1885.

Friend S., there is no way that I know of to purify wax without considerable trouble and waste. We find a good deal of dirty wax that comes in all the wax of commerce. Melting in a deep can, and dipping off from the top, is about as good as any way. Blowing steam on the residue will liberate a further quantity of darker-colored wax. In making fdn., the dirty wax collects on the steam-pipes, and on the bottom of the tanks. We have sold this to wax-candle makers and refiners, to some extent, but they allow us but little more for it than the freight. The use of acids gives us a better-colored wax, but it is hard and somewhat brittle, therefore we have discarded the use of acids in cleansing wax for making fdn. Nice clean wax, such as comes from the wax-extractor, is really worth quite a little more than the wax of commerce. We usually pay about one or two cents extra for bright clean wax from the wax-extractor.

WINTERING BEES IN A CAVE, ETC.

I received my first number of GLEANINGS to-day, and am highly pleased with it. I was led to discontinue several other bee-journals, and subscribe for yours by the reading of your A B C, which I procured from a friend. I was captivated with Blue Eyes, and more especially with the outcroppings of your home life, which the pages of your book reveal. I find the same sentiment in the copy before me in "Notes by the Way," in reference to parting with your family.

Oh the blessings of a home where old and young mix kindly! The young unweaned, the old unchilled, in unreserved communion.

Who is this Huber? A successor of Blue Eyes, I suppose, which entitles him to papa's knee. Please tell your new subscribers something about him. I would ask only one trial, to guess after whom he was named.

My bees are in fine condition. I put 36 stands in a cave last fall, and every one wintered. I had them out for a fly last week. The ground being covered with snow, I scattered hay over quite a large space of ground, and, as a result, I lost scarcely any bees. It was quite warm, and what a jolly time they did have! I never saw bees fly stronger than they. I called for Sadie to come out and enjoy the sight with me. By the way, Sadie is my better half, and, in my opinion, one of the very best women in the Hawkeye State.

FEEDING BEES BY POURING THE FEED UPON THE BOTTOM-BOARD.

My bees will need some feeding before long. I tipped the hives back slightly when I carried them back in the cave, with the view of feeding at the entrance, in a way which I have never tried. I wish to know whether I can not pour a small dipper full of syrup along the entrance, letting it flow back over the bottom-board, say once each day for a while. I fed them one evening in this way, and they took it up clean, as I could see back by holding my lantern properly at the entrance. Having no feeders, this is convenient, if no detriment to the bees results from it. I have the caps on them well packed with dry slough hay. B. F. WOODCOCK.

Pleasantville, Ia., Mar. 12, 1885.

Friend W., I do not like to hear you say you stopped other bee-journals in order to take GLEANINGS. Will it not pay you to take all of them?—If I remember rightly, I have mentioned Huber a *few* times, even to new subscribers. He is a particular friend of mine. In fact, his mother says we are devoted to each other; or, in other words, that we mutually admire each other, and I rather think it is a credit to both of us that we do. But, about that cave. Ever since I visited Mammoth Cave (and, by the way, I have got a great big story in store for the little ones in regard to that Mammoth Cave), it has seemed to me that a sensible place to winter bees is in a cave—a dry cave, like most of the Mammoth Cave, where the temperature did not vary more than one or two degrees from a steady 55. I am glad you called your wife, and I am glad, too, you put the bees back and afterward fed them. Your plan of feeding is one of the very best, providing you do not feed so much that some of it is left on the bottom-boards in the morning for robber-bees to get into. If you allow any thing of that kind to happen, you may wish you never thought of feeding, or thought of bees either, for that matter. This plan of feeding is an old device; and where the bottom-boards are tight, or where one is careful not to let it drip or drizzle outside, it is as good a way as has ever been devised.

ROBBER-BEES GOING SIX MILES.

In early days, one of our old-time bee-keepers, who was a close observer of the outside of a gum, discovered that robbers were helping themselves to the honey of one of his hives. When he saw in what direction they flew, he was greatly surprised, for it was to a small grove a mile and a half away. It was his usual custom to hunt bees. He was sure he had them trapped; but by caging a few of the robbers, and letting them have their liberty near the grove he found they went over the grove to the yard of a friend six miles away. But in those days there was no bee forage until basswood came in

bloom. The bees would rear a large number of young, entirely exhaust their stores, and frequently starve. More instances than one can be referred to where bees will fly a long distance in a time when honey is scarce.

RAISING STRAWBERRIES BY THE BARREL.

In your issue of March first I noticed an article on raising strawberries in pots. There is another way where room is very limited. Take a sugar-barrel, and around it bore two-inch holes far enough apart to give the plants room in which to grow. Fill the barrel full of rich soil, and set your plants one in each hole. The whole outside of the barrel will be covered with red and green when the fruit is ripe. If the soil becomes dry, irrigate by pouring water in at the top, and keep the top covered over with something, that the soil may not be baked by the sun. A friend of mine has three barrels arranged in this manner, and he claims they will furnish all the berries they can use.

W. S. DORMAN.

Mechanicsville, Iowa, March 10, 1885.

Many thanks for the facts you give, friend D. Your plan of raising strawberries in a barrel has been going the rounds of the newspapers, but I should be much better pleased to hear from somebody who has made it a success. You say your friend claims that his three barrels will furnish all the berries they can use. Now, if he gets a good crop of berries by the plan, please write and tell us, will you? and also please tell us if he does *not* get a good crop. Suggestions like these, that are rather odd and curious, are always finding their way into the newspapers, and they are generally copied extensively; while reports of good results obtained in the old orthodox way are passed by with comparatively little notice. I for one am in doubt as to whether any strawberries were ever raised by the barrel process. We have been trying to raise strawberries in the greenhouse; but although we make the plants grow nicely, and get plenty of blossoms, and some very small green fruit, we have not seen a ripe berry yet.

BEES COMING OUT OF THE HIVES, AND DYING ON THE SNOW.

I should like to know how to keep the bees from coming out of the hive when the snow is on the ground. I have three colonies, and I am afraid when they keep coming out whenever the sun shines. I have tried every thing that I could think of, and I think I shall try bee-keeping two or three years more, and see if I can't do better than I did last year. I had three old swarms, and they swarmed ten times, and I hived them all, but they did not want to stay. They would leave the hive, and I would hive them again; but they would leave it again, and I kept only five young swarms, and now I have three. BEN BETTEN.

Goodles, Mich.

Friend B., from your description I should think that your bees were suffering for want of ventilation, or from disease of some kind. Healthy bees seldom come out and die on the snow, as you mention, although they do sometimes, it is true, come out when the sun shines full on the entrance, when they are impatient after a long confinement. At such times, putting a broad board in front of the

hive so as to shade it will often prove a remedy. If a few bees go out prematurely, and get lost, I would not mind it. More or less are lost all the while in this way, but we do not notice it very much unless the snow is on the ground, so as to make it look more apparent.

BEES AND CARP.

Our bees had a good cleansing flight to-day. One dead, and the other 25 appear to be in good condition. This is the first good flight for two months, and the weather has been pretty cold most of the time. Much of the honey in the hives last fall was thin and watery (it being collected late in the season), and I expected some loss, but am happily surprised at what I have seen to-day. The bees look bright, and the colonies appear to be strong. I am very much interested in the articles on German carp, which I read in GLEANINGS. I shall want one of your books on carp culture when it is ready. I have a pond of about 6 acres in extent that I stocked with carp 3 years ago last fall, but have not seen one of them since. There are a few other fish in the pond. B. DOWNS.

Naugatuck, Conn., March 4, 1885.

OUR 75-CENT TELEPHONES.

The telephone we got of you worked well to our bee-house, 600 feet away. Now our bees are gone, we have moved the wire to my brother-in-law's house, about as far again away, but we can only just distinguish a sound, but no words. That, of course, does not suit us. Have you one that will work well 1200 or 1300 feet? MRS. J. HILTON.

Los Alamos, Cal., Dec. 22, 1884.

I do not believe our little telephone will work well for more than 600 feet, my friend; and as we keep these principally to tell when bees are swarming, I do not believe it would be best for us to go into more expensive telephones. I am some in doubt whether you can get any *sound* telephone to work successfully for much more than the distance mentioned.

MAKING THE ROADSIDES BEAR HONEY-PLANTS.

It has often occurred to me, that scattering seed of honey-plants by the wayside is very wasteful as regards the seed, as a very large proportion will fail to get a hold, or ever amount to anything. Would it not be worth while to have an instrument (which might be useful in the garden also), something like a walking-stick, with one or more metal claws, to give the earth a little scrape, and break ground for the seed, which could be contained either in a hollow tube in the instrument, or a barrel at its end, operated on swivels by a wire attachment, and arranged to let loose a certain quantity at a time, to run into a guide-pipe conducting it to about an inch from the point of the instrument. It seems to me a much larger proportion of seed would take this way; and if we sow seed to beautify the landscape, we need not do it surreptitiously. I make the suggestion, so you can take it for what it is worth, as I think you are a very competent judge, and have every facility for experiment.

R. W. McDONNELL.

Galt, Ont., Can., March 10, 1885.

Friend M., your arrangement would answer very well for a certain class of seeds, no doubt; but for seeds as tenacious of life as clover, for instance, I think the better

way is to broadcast it just before a shower of rain. Seeds that will not readily make their way through grass and weeds had better be started as we do other crops; namely, plow and harrow your roadsides, and cultivate your plants until they get started. It is not very uncommon in our vicinity to see a good crop of potatoes raised along the roadside, and I for one like the idea of seeing cultivated plants take the place of useless weeds; and while you are about it, why not dispense with the fences, and put your cultivated honey-plants clear up to the wagon-tracks? I do not believe your instrument for stirring up the soil will do very much good while the ground is full of grass and weeds.

CROWDING OUR CHILDREN AT SCHOOL.

The crowding at school, spoken of by Mrs. Chad-dock, on page 53, is a great evil, and, I fear, a growing one; and it is not confined to examination day, nor to young children. Pride in the progress made by the pupils of the school has much to do with it. One of the celebrated normal schools of the State of New York belongs to this class. Its principal has been heard to say, that if the pupils came out alive that was all he cared, and he suits his actions to his words. One, at least, of the pupils of that school, died of overwork, before completing his course—murdered by that merciless system of crowding. And comparatively few, possessing energy and ambition, can complete a course at such a school without shortening life, and rendering it burdensome by means of an enfeebled constitution. I am thankful that this is not a necessary condition of a good education. If it were, I should rather my child should learn only "the three R's—Readin', 'Ritin', and 'Rithmetic.'" BURDETT HASSETT.

Howard Center, Iowa, Feb. 10, 1885.

SCORPIONS.

On p. 96 you evince a curiosity to know more about scorpions. From the references to them found in the Bible, as well as from writings of travelers and others, I judge that the scorpions of the Old World are much more venomous than those found in Florida and others of our Southern States. The sting is a short, bony, curved claw at the extremity of the tail, and is used by striking. Drumming on the table smartly with your bent forefinger will give a very good idea of the rapidity and manner in which they work their tail while stinging. The sensation caused by their sting is said to be similar to that caused by the thrust of a red-hot needle in the flesh, the pain lasting about a minute only, leaving no other effect after it, as do bee-stings. Old residents of that section dread them but little, simply being careful not to knowingly handle or sit down on them. The presence of one in the toe of a boot, while it is being pulled on in the morning, is pretty certain to give bystanders a chance to laugh tears. If you will send a small wide-mouthed bottle of alcohol to Friend Hart, I presume he will willingly return it to you with one or more of the little rascals in it. O. O. POPPLETON.

Williamstown, Iowa, Feb. 5, 1885.

Many thanks, friend P. I am very glad to know that scorpions, at least those with you, are no more dangerous than you put it. It would seem, then, that there is no poison exuded by the scorpion—perhaps only a poisonous substance incorporated in the claw.

REPORTS DISCOURAGING.

BAD REPORT FROM FRIEND MALONE.

BEES all dead, friend Root. You can make room for Blasted Hopes this spring. Out of 231 colonies last fall in our township there won't be 50 that will pull through the winter, though I must confess that the trouble is mostly carelessness. This winter beats the winter of 1880, bad. I have 8 colonies in a clump, and have lost 18 out of 30 on the summer stands.

Oakley, Iowa, Feb. 23, 1885. WM. MALONE.

ONLY 3 LEFT OUT OF 26.

I went into winter quarters with 26 good colonies; to-day I have three left, and about 300 combs, some Langstroth and American. This was the honey-dew, and nothing else. Those that had old honey from the year before are all right now. What plan shall I take to fill my boxes with bees? I have no spare money to do this, as I lost my property last June, and now I've lost about all my bees; and when summer comes the worms will be hard to keep out. Please tell me what is best for me to do, to make a start again.

F. SHILLING.

Jewett, Ohio., Feb. 28, 1885.

Friend S., you can fill your hives from the three you have left; but you would get along a little faster if you had a few more, and it may be best for you to purchase a few. Instructions for building up are given in the A B C book, and our back volumes contain many reports of those who have built up with wonderful rapidity from a very small number, after heavy losses in the winter.

ALL DEAD BUT ONE.

I took the frames out of the upper story, and filled them with rags, about four inches thick, and with planks around them except in front, which was to the south-east. I thought they were all right, but the winter took all but one. Two had no honey; two had honey in the outside frames, and two had some molasses, which I gave them in the fall, in the middle frames, and sealed honey in two of the outside frames. I have not heard from others lately, but some had lost several before I had lost all mine. I shall try again.

GETTING SPIDER-PLANT SEED TO SPROUT.

I divided the spider-plant seed with five who have frames, but not a single grain sprouted.

F. SIEFFER.

Campbellton, Mo., March 2, 1885.

Friend S., packing the bees up with rags, and fixing them up with planks and all sorts of protection, is only time wasted, when the amount of stores is insufficient, and I judge it was insufficient, or of poor quality, with the seven colonies that you lost. Don't use molasses, or any thing of the sort, for winter feed, but give them granulated sugar until they have sealed stores on both sides, behind and before, and overhead and under foot; and then when a blizzard comes and lasts for five or six weeks, they can not possibly miss their stores.—Your spider-plant seed will probably come up yet. It is a queer grower. It has acted very slow and sluggish in coming up in the greenhouse with us, but we have finally got a pretty good lot of plants by waiting some time for its slow motions.

A COMPLAINT THAT GLEANINGS COMES TOO OFTEN.

Last spring found me with 150 swarms of Italian hybrid bees in Langstroth hives, increasing during summer to 175 swarms, and about 700 lbs. surplus honey, mostly extracted, from one and two pound sections incomplete, or imperfectly filled. During the drought of summer they were fed liberally with sugar syrup, and by that means were made strong for work on fall flowers, and stored ample supply for winter, and a very small surplus; but, about 40% froze to death the last half of February, and many more are so weak that they will either die or are too much reduced to do more than build themselves up for another winter. The general failure of the honey crop all over the country, except it may be in one or two remote localities, followed as it is by unprecedented low prices, causes me to turn away from apiculture with disgust, and I do not care to be reminded of the business every 15 days by a new GLEANINGS. The whole thing is "gleanings" indeed, and of the leanest, thinnest kind. I don't want to think of it. Send the paper the remainder of the year (Aug. next) to ———.

Quincy, Ill., Mar. 4, 1885.

J. D. WALDO.

Friend W., I know your experience has been a little discouraging, but you have reported for only two seasons. Very likely your next season would place you away above board. But if you prefer not to try it any longer, it is all right, and we will send GLEANINGS to another address. But, my friend, before closing may I remind you that all kinds of business have their vicissitudes? Lines of industry like bees, dependent on the weather or other accidental circumstances, perhaps have more ups and downs than some others; but at the same time there is also a possibility of greater results. You rather make light of our plan of *gleaning*; but I suppose you know that these very gleanings, many of them, tell of single small apiaries yielding a larger income than large farms. Facts from actual experience are needed to bring out the truth of any science or industry; and this very letter of yours is an important factor in the general fund of knowledge. I am inclined to think we shall hear from you again, even if you do sell out. Sooner or later you will long for the "merry hum" once more.

One-half of the bees in this section are dead, and most of the rest more or less diseased.

Hudson, Mich., Mar. 12, 1885. J. C. DICKINSON.

HONEY-DEW FOR WINTER STORES.

About 90 per cent of the bees that went into winter with honey-dew, are dead, as far as I can learn (and about 75 per cent of the bees with white clover honey to winter on are alive). This is not very satisfactory, but it proves honey-dew to be poisonous as a winter food for bees. There are not bees enough left in this county for seed, which will make honey scarce next year.

C. J. CLARK.

Bowling Green, O., March 11, 1885.

OUTDOOR WINTERING VERSUS CELLAR WINTERING.

Bees have wintered very poorly here, more have died than in any winter for a long time. I think more than half the bees are dead in this neighborhood, and I feel safe in saying that the bees that have wintered outdoors with good protection are coming out better than those wintered in cellar or house. Some of our most experienced bee-raisers

are having the poorest luck, and I think it is the result of extracting honey from the brood-chamber during the honey season, and trying to supply nature with syrup.

SYLVESTER COOK.

Cox's Mills, Ind.

Friend C., extracting the stores from the brood-chamber, and leaving nothing, is certainly *very* bad policy; but if we take out the honey and give them sugar instead, before cold weather sets in, I think we are ahead of nature. Our methods should harmonize with nature, and with the wants of the bees. God has placed us here on this earth to improve on nature, or, if you choose, to assist and develop nature. Bees in hollow trees, where nature has full sway, do not by any means winter successfully.

A 16-YEAR-OLD BOY BEE-KEEPER, AND THE REASON WHY HIS HOPES ARE NOT BLASTED.

I am a boy only sixteen years of age, and so of course I do not know any thing about bees. I commenced last season with 2 colonies; increased to 4, and took about 5 lbs. of honey. I put them into winter quarters about Nov. 20, with lots of honey, and to-day I find but one alive. How is that for cellar wintering? But in spite of all this, we have got plenty of *price lists*, and *girls* too, in this part of Minnesota, so our neighborhood is not so cold as friend Smith's and Pasley's.

SETH WINQUIST.

Atwater, Minn., March 10, 1885.

I suppose, Seth, the reason why you are still cheerful is, that the plenty of price lists you mention tell you where bees can be bought cheaply, and those girls do their part by making *any* boy feel ashamed of himself if he attempts to put on a long face, or tries to look any thing like blasted hopes, with the world all before him. God bless the girls as well as the boys! There are battles before them to fight; but with the help of Him whose strong arm never fails, the end shall be victory.

50 SAVED OUT OF 70.

Many bees have perished during the winter. Out of 70 colonies I have about 50 left. Many that had 2, 5, or 10, report all dead, others pretty nearly all gone. Even some noted bee-keepers have lost heavily. I lost four in your chaff hives; had plenty honey; think they were smothered by snow. They had a good fly the other day; had dysentery badly. I had taken the pollen out, but I think it will be the last time I'll do so. Your reversible frame, I think, takes the lead for the present.

S. H. BOLTON.

Stanley, Ohio.

Friend B., you say four in chaff hives had plenty of honey. Now, this "plenty of honey" may have been honey-dew honey, may it not? If any one has had bees die in chaff hives, when fed up heavily on a syrup made of granulated sugar, and the feeding done during warm weather, I should like to hear the particulars. I do not believe that removing the pollen had any thing to do with your losses; that is, I do not believe it made them worse.

ONLY 6 LEFT OUT OF 24.

My report for winter of 1885 is this: Fall count, 20 colonies and four nuclei; spring count, 6 colonies. This is a little bad, but yet I am not discouraged; will try it again.

A. L. LINDLEY.

Jordan, Jay Co., Ind., March 14, 1885.

HEAVY LOSSES IN CANADA.

I am sorry to report that bees have not wintered well in this part of Canada (Ridgeway is situated on the line of the G. T. Railway, 18 miles from Niagara Falls, and 12 miles from Buffalo, N. Y.). I am unable, at present, to tell you just what the losses have been in other parts of the province; but I should not be surprised to learn that they have been severe. I have taken some trouble to "take stock" of this vicinity, and find the loss about 60 per cent. Dysentery is quite prevalent, although some have died from other causes. My yield this last season was about 86 lbs. of comb honey, spring count, principally from white clover. Basswood yielded sparingly, but we had a good flow from fall flowers.

J. F. DUNN.

Ridgeway, Ont., March 12, 1885.

ONLY 2 LEFT OUT OF 17.

My report for this spring is not very flattering. I have two swarms left out of 17. The honey was mostly eaten up in the brood-chamber, but plenty in other parts of the hive. They were all dry inside the hives, but I think the cause of their dying was that they ate all the honey in the cluster, and the weather was so cold that they could not get to other parts of the hive to get honey. The weather has been very cold here—36° below zero, and some days an average of from 16 to 15° below. Inclosed please find my order for a wax-extractor, for you can plainly see that I am in need of one.

E. W. OSBURN.

North Adams, Mich., March 13, 1885.

Friend O., we are glad to sell you a wax-extractor, but I would advise you to be not hasty in melting up your good combs. By and by you will get the mastery over this wintering trouble, and then your good combs will be needed. They will keep a lifetime, if properly cared for.

CHAFF-PACKED HIVES NO BETTER THAN COMMON ONES.

There is a great mortality among the bees in this locality this winter. Every one I have heard from has met with a partial, and many of them a total loss. The winter has been unusually severe on the little fellows, from some cause or other. I have lost 8 out of 17. I see no great difference between the chaff and common hives. Some, as strong stock as I have, I did nothing to in the fall; some in chaff are very weak, whilst all have honey. It will require care and attention to bring them through.

JOHN COULTER, SR.

Oxford, Ohio, March 16, 1885.

Do not be in haste, Friend C., to draw conclusions, especially with so small a number of bees. If your bees are put away as directed in the A B C book, I am inclined to think the losses will not be very heavy.

ALL DEAD IN CHAFF HIVES, BUT ALIVE IN SIMPLICITY.

Can you give me an idea of what is the matter with my bees? I have lost 10 colonies in chaff hives, while the bees in Simplicity hives, with a little chaff over them, are all right, and in as good shape as when put up in the fall. They have plenty of stores, but the honey is bad—nearly all honey-dew. Do you think the honey-dew killed them? I have made candy from granulated sugar, and fed those I have left. The chaff hives had cushions and loose chaff over them, and the full width of entrance left

open. Several bee-keepers here have lost their entire apiary in the last six weeks; others one-half. Outlook seems to show very few live bees for spring in this locality.

E. F. WILCOX.

La Grange, O., Feb. 19, 1885.

Friend W., I should say it was the honey-dew that killed them, without question; but I confess myself unable to give any explanation as to why the bees in Simplicity hives should have fared better. Were their stores exactly the same as the others'? We remember your locality as one where honey-dew was plentiful. I think stores of sugar syrup in place of the honey-dew would have saved them. See the report from your neighbor Dan White, in another column.

"Wherefore Hanun took David's servants, and shaved them, and cut off their garments in the midst hard by their buttocks, and sent them away."—I. CHRON. 19: 4.

That is just as we bee-keepers feel here in Harrison Co., this spring, for the bees come up missing. I will give you a report of 5 apiaries. Mr. Cavin, 60 in fall; spring, 0. Montear, 70 in fall; 2 left. Shilling, 28 in fall; 2 left. Hines, 50 in fall; half gone, last report. Self, 12 in fall; 4 yet.

So let the wide world wag as it will,
We'll bee gay and happy still.

Jewett, O., Mar. 23, 1885.

DAVID LUCAS.

REPORTS ENCOURAGING.

FROM 56 TO 76, AND 700 LBS. OF HONEY.

LAST year was my first year's experience with bees. The bees that I have got do not belong to me. I am working them on shares. Last spring I started with 56 colonies, which I increased to 74. I extracted about 700 lbs. of honey. We have very good indications of a good honey season this year. I saw drones in our apiary on the 2d inst. Bees were gathering pollen very rapidly on the 4th inst. We had some very hard weather here lately. The snow fell 3½ inches deep; on the 12th inst. the wind was from the north-east, consequently the snow blew in and blocked up the entrances, but I cleaned them out. Would it have hurt them to have left them alone until the snow melted, which it did in about 48 hours? My bees are in Simplicity hives.

F. S. ELDER.

Lake Village, Ark., Feb. 19, 1885.

Friend E., the snow around the entrance will do no harm, no matter how long it is left. The snow is so loose and porous, that the air always gets through in sufficient quantities. Disturbing or brushing the snow away may stir the bees up, and do harm. Don't meddle with the snow.

E. SANDFORD'S REPORT.

I went into winter quarters with 73 colonies—6 nuclei and 30 rather weak; all seem to have wintered very well, with the usual amount of dead bees in each colony. I wintered mostly on 10 frames, whether weak or strong. I use the 10-frame Simplicity hive; and in fixing for winter I took off the enameled cloth and put on a very thin muslin, and that so late that they could not wax or seal it before cold weather. I then filled the top story with corn silks, well pressed down, leaving the entrance 8x% open. The advantages this method of packing has over cushions are, there are no crevices, causing

too much direct ventilation, by which one of our most learned and scientific bee-men in this neighborhood has lost heavily this winter. So far this has been a hard winter on bees. I know of but two who have not lost heavily. This is my first report. Nokomis, Ill., Mar. 6, 1885.

E. SANDFORD.

FROM 25 TO 40, AND 2770 LBS. OF HONEY.

I must say a word for my bees. Last April, when I returned from Florida, I found them all alive but two colonies, 25 in all, generally in good condition. Bee-men in general complained of the season being very poor. As for myself, I have no reason to complain. I extracted 1740 lbs.; comb honey, 1030 lbs., which makes 111 lbs. and a fraction to the colony, spring count. From one-half to two-thirds of my honey the past season was made from red clover; the rest from white clover, our only source of honey in this part of the State. I have increased the past season to 40 colonies, all strong, and full of honey at this writing.

J. F. MILLER.

Millersburg, Ky., Feb. 23, 1885.

MY REPORT FOR 1881.

We commenced the season with 6 colonies, and increased to 18; sold 4 of them for \$50.00 before we extracted any, and from the 14 that were left we extracted a little over 1200 lbs., so we have now 14 to commence with this year. How do you think this will do for a beginner?

MRS. P. H. HALL.

Luling, Texas, March 16, 1885.

Tiptop, my friend.

ONLY ONE LOST OUT OF 81.

I have lost only one colony out of eighty. My bees are in the best condition I ever had them at this time of the season.

MAD TALBERT.

Morristown, Ind., Mar. 9, 1885.

ONLY TWO LOST OUT OF 75.

Bees in this section are faring rather hard this winter. I have lost only 2 out of 75, up to date, but I hear that many around here have lost heavily, while others have lost all.

N. CASE.

Orangeville, O., March 9, 1885.

A GOOD REPORT FROM MISSOURI.

To-day I examined four swarms of my bees to get them to rearing drones; some are rearing brood, and one had sealed brood. I never saw bees in finer condition, nor stronger, so early in the spring. I have 35 colonies, all are alive, and took a good fly to-day. Bees are packed in chaff, and no dead colonies. I shall run 100 nuclei for queens this summer, and more if needed.

G. A. BEECH.

Quiltman, Mo., Feb. 27, 1885.

NOTES AND QUERIES.

A QUESTION FOR FRIEND DOOLITTLE.

IN GLEANINGS, Feb., 1885, Mr. G. M. Doolittle, in his article on comb honey, says he puts 5 or 6 frames of empty comb for a new swarm. What does he do with the remainder of the space?

Does he put in the remainder of the frames empty, or does he put in division-boards? An answer would greatly oblige. I consider Feb. 1st No. of GLEANINGS worth the price for a whole year. Set me down as a life subscriber.

E. W. JAMES.

Summit Grove, Ind., March 9, 1885.

[Thank you, friend J. I presume friend D. meant to use a division-board; but if the colony were large enough, and needed more room, I think he would put in more empty combs. Will he please answer?]

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER.
MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, APR. 1, 1885.

He that taketh not his cross, and followeth after me, is not worthy of me. — MATT. 10. 38.

VIALLO'S NEW FACTORY ALREADY STARTED.

The following is at hand just as we go to press: My new factory is just completed, and I have steamed up this morning, and I am again in running order, except for sections. V. L. VIALLO.

Bayou Goula, La., March 23, 1885.

That is what I call business, friend V. Such energy deserves encouragement, does it not, boys?

C. R. ISHAM, Peoria, N. Y., sends us samples of some very nice wooden separators, about 1-16 inch thick. These separators, he states, are cut from well-seasoned lumber, and will therefore keep straight. The prices of these separators are 50 cts. per 100, or \$4.00 per 1000.

STINGLESS BEES.

THE newspapers get hold of these about once in so often, for a sensation, and then the item goes the rounds. These bees do not amount to any thing. They have been carefully tested; and although it is true, they do not sting, it is also true that they do not gather any honey of any account. There is no rose without its thorn.

MAIL, EXPRESS, OR FREIGHT.

WHEN making an addition to an order you have previously made, or when referring to something you have had or ordered, please state whether by mail, express, or freight, for a separate set of clerks are employed on each department, and much time will be saved by saying how you ordered the goods sent.

OUR OWN APIARY.

We are happy to say that our apiarist, Mr. Wm. Kimber, has gone thus far with his 198 colonies, with the loss of only 7. With reasonably fair weather, the probability is we shall not lose any more. The evidence is heavily in favor of stores of granulated sugar. Neighbor H. has lost nearly half of his River apiary, and we think it was owing almost entirely to the stores of honey-dew honey.

A JOURNAL ON CARP CULTURE.

A NEAT little sheet comes to us from the neighboring town of Akron, O., entitled, *National Journal of Carp Culture*. There is a real want for a journal on carp culture, and we gladly welcome the new comer among our rural class journals. The abundance of beautiful springs in the vicinity of Akron would, we should suppose, give wonderful facilities for making carp-ponds, especially in keeping the water at a uniform level the year round; for these soft-water springs of Summit County are, as a rule, never-failing. I presume the editor has, of course, a pond or ponds of his own, in order that he may give us the benefit of his practical experience in the new industry, but I do not find any mention of it in this first number.

BUDDING AND PRUNING KNIVES.

We have just added to our counter store, knives for the above purpose, made by the celebrated Northfield Knife Co., expressly for us. We have three pruners and one budding-knife. The heaviest pruner, which has a metal plate on the lower end, and is heavy enough to drive a pretty good-sized nail, is 75 cts. The next size to this above is 35, and the smallest 25 cts. Budding-knife, 25 cts. If wanted by mail, the postage on the above knives will be 6, 5, 3, and 5 cts. respectively. My name is put on the blade of each knife, and I do not hesitate to guarantee them equal to any thing made, as to steel and temper. We are enabled to give the above low prices because we buy them in large quantities.

BUSINESS AT THE PRESENT DATE.

I AM glad to be able to say, that although we have been a little behind, we have now caught up on every thing, unless it is a few orders for odd-sized sections, which have been delayed on account of the difficulty in getting lumber sufficiently seasoned fast enough. As we have now fine weather, by the time this reaches you we hope to have every order clear up. Well, as we are so much abreast of the season, we extend the discounts on foundation-mills, sections, and comb fdn., 10 per cent from list prices, until our next issue. Beeswax is still low, compared with former seasons, probably, somewhat, on account of the loss of so many bees. May be we shall be enabled to carry the above discounts through the entire season. We will if we can; but demand and supply must regulate the matter.

THE NEW WEEKLY "CANADIAN BEE-JOURNAL."

WE have long expected that friend Jones would be obliged to publish a bee-journal, sooner or later, but we did not quite expect it would start out to be a weekly bee-journal at the outset. So it is, however. We have the following from friend Jones to-day:

We suppose that you have, of course, heard that we are going to have a CANADIAN BEE-JOURNAL. Canadian bee-keepers have been at us incessantly to start one, for many years past, and we have at last decided to try it. It will consist of some number of pages as yours, and at same price. There will be half the number of pages in each number, but it will be issued weekly instead of every two weeks. We want to work in unison with all our brother-publishers. We know that we can with you. We intend publishing first issue about the first of April. B. A. JONES & Co.

In friend Jones's prospectus we find the following sensible remarks:

Though it may ultimately prove a source of fair recompense for the amount of labor expended, it will be some years before it does so, and you all know that it is not a pleasant prospect to look forward to that of working for years for nothing. We do not enter the field expecting to "make money," but for the sole purpose of *WARMING* the proud position which apiculture has attained in the Dominion of Canada, and for the purpose of the better advancing the allied interests of all engaged in the business.

THE A B C OF POTATO CULTURE.

THIS is to be a book of 50 or 60 pages, size and style of the A B C book. It is written by Mr. T. B. Terry, the successful farmer and potato-grower of the State of Ohio. Mr. Terry is employed most of his winters in giving lectures before farmers' institutes, and he is always authority on any thing connected with agriculture. The book is not only a valuable one to potato-growers, but a great part of it applies to the management of almost any crop on the farm, especially to the preparation of the soil, manures, etc. Mr. Terry reminds me a good deal of friend Hutchinson's early writings. He is emphatically opposed to farmers investing largely in commercial fertilizers, new-fangled seeds, and, to a

considerable extent, in new-fangled machinery. His advice is, to make your own fertilizers on the farm. Take good care of that which you have already; make two blades of grass grow (or two potatoes, if you choose) where one grew before. Make the most of what you have got; and when you get a little money ahead, then try the novelties cautiously, if you have a mind to. Price of the book, 35 cts.; by mail, 40 cts. We expect to have it ready to mail by May 1.

ORDERING HEAVY MERCHANDISE BY EXPRESS.

TROUBLES have already commenced in this direction. Almost every day one or more of the friends order 500 or 1000 section boxes by express. Well, unless the order goes to the South, and in the majority of cases it does not, we know before the goods are started that the express charges will be a great deal more than the goods are worth—sometimes more than double. What shall we do—write and explain before shipping, and take the risk of being told that the one who ordered knew his own business, and would thank us to ship as directed, or shall we obey orders, and then have the sender refuse to take the goods because the charges are so much more than he expected, leaving us to pay the enormous sum ourselves? We have tried all sorts of ways, but none of them always meet with approval. If when you want something by express that is very heavy, and on account of particular circumstances are willing to pay charges a good deal more than the thing is worth, if you will so state it will make our duty plain and easy. For instance, suppose you say, in ordering 500 sections by express, "I know the charges on these goods will be fearful, but I want them for a particular purpose, and am willing to stand it." You see, we do not know whether you are posted in ordering goods, and know just what you are about, or whether you said express charges without thinking or knowing that such bulky goods are *never* sent by express unless some special contingency demands that they should be on hand instantly, without regard to cost.

REVERSIBLE FRAMES, AGAIN.

It pains me to see so many working on this matter, and taking the trouble to send me models not only of what has already been done, but working on something that has been ruled out by universal consent. For instance, a great part of the whole number are for using frames at fixed distances from each other, whereas the majority of bee-keepers have decided that fixed distances can not be tolerated. Another class have an arm, of wire or metal attached to each of the four corners of the frame. I believe this has been decided by universal consent to be too much machinery. Another class hitch the arrangement to the top-bar, which is simply nailed in the end of the end-bar. If you use a reversing device, it needs to be attached to the *end-bar*, for obvious reasons. Still others send us something that will mash the bees, or cut them in two across the rabbet. I should rule out all these. Another large class propose having a supporting-arm half way down the frame, and the rabbet or strip of metal fixed half way down the end of the hive to hold it. This is old and discarded, but it comes up in new forms several times a day. Our friends of the *B. B. J.* come the nearest to making this practicable by making the bottom story of the hive half depth. Frames can be handled very well in such a hive;

but the cap, or top-story, must slip down over the upper half of the frames. Now, when the bees build fins of comb from the upper part of the frames to this cap, or half-story, what are you going to do when you want to take off said cap? Heddon's arrangement, and the one we are making, seem to me to be the only practical devices yet submitted, although the number sent in is hundreds. One thing more: Whatever device is adopted should permit us to use both frames and hives already in use, and should be so it can be attached to the frame without nails or screws, or boring more than one hole at each end-bar. This would rule out friend Heddon's arrangement, but our own would fill the bill.

We have to-day, March 30, 6234 subscribers.

CONVENTION NOTICES.

The bee-keepers' association of North-Western Indiana will meet on Wednesday, the 8th day of April, 1885, at 10 o'clock A. M., and 2 o'clock P. M., in the jury-room at the Court-house, in Laporte, Ind.

A. FAHNSTOCK, SEC.

On account of the prevalence of smallpox in the city of St. Joseph, Mo., the semi-annual meeting of the Western Bee-Keepers' Association will be held at the Court-house in Independence, Mo., April 23 and 24, 1885.

C. M. CRANDALL, SEC.

The Elbert Co. bee-keepers will hold their next meeting in the Grange Hall, at Bowman, Ga., April 4, 1885. All interested are invited to attend and make the meeting as interesting as possible.

W. R. HENDRICKS, Pres. J. A. DILLASHAW, Sec.

The Linwood Bee-Keepers' Association will be held at Rock Elm Center, Wis., in Condit's Hall, May 4, 1885, at 10 A. M. All interested are cordially invited to attend, and make the meeting a profitable one. Prominent bee-keepers are expected.

B. J. THOMPSON, SEC.

The second annual meeting of the Western New York and Northern Pa. Bee-Keepers' Association will be held at Cuba, N. Y., Tuesday, May 4, 1885. A very large attendance is anticipated, as many prominent bee-keepers are located in this territory, and are members of the organization.

W. A. SHEWMAN, Sec'y.

* SNAKED + SECTIONS. *

ONE-PIECE, V-GROOVE.

FIRST CLASS IN EVERY RESPECT.

They took first premium at Michigan State Fair last September. Every apiarist who uses them once wants no other. Will send two samples by mail for 4 cts. postage, or 1000, 44, for \$4.00. Regular price is \$1.50; per 5000, \$21; per 10,000, \$40. Send for circular, etc. Address

BERLIN FRUIT-BOX CO.,

6-84 Berlin Heights, Erie Co., O.

PLEASANT-VALLEY APIARY.

ALBINO AND GOLDEN ITALIAN QUEENS.

Untested, after June 1 to October.....	\$1 00
Per one-half dozen.....	5 00
Tested, Each.....	2 00
Select Tested, large and Light-colored.....	3 00
Full Colonies in Langstroth or Simplicity hives.....	8 00
Nucleus Colonies no queen, two-frame.....	2 25
" " " " Three-frame.....	3 00

Safe arrival guaranteed, and all orders filled on short notice, or money returned. Golden Italian Queens, reared in my home yard of over 70 full colonies (all pure), and the Albinos in my distant Apiary. Our winters are long and severe; my strains have stood the *test of hardiness*, as I have always wintered on summer stands, and have not lost a single colony in the past 4 years. Sample of my large light-colored workers sent for 10 cts.

Address E. L. WESTCOTT,
FAIR HAVEN, RUTLAND CO., VT.

BEESWAX.

Made into Given foundation on shares or for cash, on favorable terms. Best machinery, experienced hands. Western bee-keepers, please take notice: save freight or delay, and secure an article as good as any for all purposes.

JOHN BIRD,
Bradford, Chickasaw Co., Iowa.

J. W. K. SHAW & CO.,
LOREAUVILLE, - IBERIA PARISH, - LA.

We are at this date (March 16) sending out tested queens. By the 1st of April will be able to supply all demands for untested by return mail, from our choicest strains. Tested, \$1.50, \$2.00, and \$3.00. Untested, \$1.00. Special rates to dealers on $\frac{1}{2}$ doz. and dozen orders.

OLD TYPE FOR SALE.

We have still on hand 76 lbs. of our old nonpareil type for sale. For a sample of it, see any number of GLEANINGS previous to May 15, 1884. Also 17 lbs. of Italic, if desired. As it is all packed, we can not divide either lot. The Roman includes 5 lbs. and over of "logotypes," that is, the words *the*, *and*, *that*, *ing*, *tion*, etc., are made all on one body, thus facilitating composition. We offer the lot at 20 cts. per lb.

A. I. ROOT, Medina, Ohio.

WANTED, STUDENTS, Ladies or gentlemen, to learn PRACTICAL RAILROAD and COMMERCIAL TELEGRAPHY. Line and instruments furnished free. Board reasonable. Address

MR. and MRS. A. R. UNDERHILL,
La Grange, Lorain Co., Ohio.

Send for circular and price list before purchasing.

MILLER BROS & CO.,
5-5-9d Dryden, Mich.

JOB LOT OF WIRE CLOTH AT GREATLY REDUCED PRICES.

Such a brisk demand has sprung up for this, and our customers seem to be so much pleased with the goods, we have succeeded in getting another still larger lot, of one of the largest manufacturers of wire cloth in the world. Please bear in mind that the only way in which we can afford to sell it at the very low price of 1½ cts. per sq. ft. is by selling the entire remnant just as it is put up. We have now in stock the following pieces. As fast as it is sold, each piece is crossed out, and the next issue will show what remains.

Width, 8 inches. 3 rolls containing respectively 50, 50, and 60 square feet.
Width, 10 inches. 1 roll, containing respectively 72, 70, 65, and 75 square feet.
Width, 11 inches. One roll, containing 80 square feet.
Width, 12 inches. 2 rolls, containing respectively 90 and 100 square feet.
Width, 16 inches. 1 roll containing 130 square feet.
Width, 19 inches. 1 roll, containing 150 square feet.
Width, 22 inches. 2 rolls, containing respectively 250, and 180 square feet.
Width, 26 inches. 5 rolls, containing respectively, 215, 210, 216, 215, and 216 square feet.
Width, 28 inches. 1 roll, containing 234 square feet.
Width, 28 inches. 4 rolls, containing respectively, 316, 300, 290, and 316 square feet.
Width, 16 inches. 3 rolls, containing respectively, 320 and 166 square feet.
Width, 42 inches. One roll, containing 245 square feet.

KIND WORDS FROM OUR CUSTOMERS.

OUR TEN-CENT POULTRY-BOOK.

Send me two more poultry-books, and charge the same on No. 8, page 356. S. H. CORBIN.
Fabius, N. Y., Feb. 12, 1885.

OUR \$3.75 PLATFORM SCALE.

Our dealer sells the scales for an even \$10.00. The freight on 45 lbs. was \$1.15. W. G. HAYES.
Pleasant Mound, Ill.

GLEANINGS AS AN ADVERTISING MEDIUM.

My advertisement of Dec. 15, 1884, brought me between 15 and 20 answers. I am not experienced in the advertising business, but I thought that pretty good. FRED F. ROL.
Jordan, Ind., March 24, 1885.

I am going to have more work than I can stand, and I may as well set up some of the brakes now. GLEANINGS is a little too good sometimes, as an advertising medium. E. M. HAYHURST.
Kansas City, Mo., April 4, 1885.

OUR 75-CENT TELEPHONES,

To Tell When the Bees are Swarming.

This instrument is a success, as many of the friends have testified. Prices by mail are 16 cents extra. Each instrument consists of two sounders, with 100 feet of insulated wire, etc. If you want more wire, we have it put up on spools of 100, 200, and 300 feet each. Prices 16, 30, and 45 cts. per spool. If wanted by mail, postage on the spools is 5, 8, and 11 cents respectively. The 300-foot spool, in addition to the 100 feet that goes with every instrument, is probably as great a length as is advisable with these cheap instruments. This wire is made of composition especially adapted to these small telephones. A single wire running through your apiary will tell anybody in the room where the sounders are, at once when the bees are swarming. If the house is still, it could easily be heard in the adjoining room. The instruments are probably equal to any in the market, for such short distances, for a speaking telephone. But, please remember they are not practicable for much over the 400 feet mentioned. When every thing is very still, in the night for instance, they can be used for conversation as much as a quarter of a mile away. You can turn corners with them, if you wish, but some of the sound is lost at every turn.

A. I. ROOT, Medina, O.

The North-Shade Apiary

Holds the field this spring. Our bees have wintered well on fall honey and honey-dew (bees are Italians). Full colonies in either the L. or the Gallup hives, for May delivery. Nuclei, Queens, and bees by the pound, for the season. Price List Free. 8-911d
O. H. TOWNSEND, ALAMO, CAL. CO., MICH.

FOR SALE. DOLLAR QUEENS, AFTER APRIL 1.

And \$2.00 Tested queens from one of A. I. Root's best imported, or from a tested Cyprian. 8d

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ads. intended for this department must not exceed 5 lines, and you must say you want your ad. in this department. We will not be responsible for any error.

WANTED.—To exchange, for bees by the pound, nuclei, or full colony, any of the following nursery stock: 2-year-old apple-trees, 3 to 4 ft.; 2-year-old plum-trees, 4 to 6 ft.; orange quince, 2½ to 3 ft.; Evergreens, Arborvitae, Norway, and Black spruce, 1 to 2 ft., just right for hedges and screens. Also Cuthbert raspberry and strawberry plants and flowering shrubs, vines, etc.

8d D. G. EDMISTON, Adrian, Lenawee Co., Mich.

WANTED.—To exchange Brown Leghorn eggs (from stock of W. E. Banney), for Italian queens or bees. W. H. OSBORNE, Chardon, O.

WANTED.—To exchange 4-piece dovetailed sections for bees or Italian queens. 8d W. S. WRIGHT, Battle Creek, Mich.

WANTED.—To exchange. I will exchange a first-class Organ and a good Melodeon, or back VOLUMES of GLEANINGS, *American Bee Journal*, and the Poultry journals, for bees in L. frame; also fancy exhibition coops for bees. Make offers. H. S. HOUSE, Manlius, Onond. Co., N. Y.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough for these queens to pay for laying them up and keeping them in stock, and yet it is often thus quite an accommodation to those who can not afford higher prices.

QUEENS FOR SALE.—Hybrid queens, 50 cts. each; black queens, 25c. each, from June 1 to Oct. 1. Safe arrival guaranteed. R. H. BAILEY,
7-11db P. O. Box 81, Ausable Forks, Essex Co., N. Y.

Three tested Italian queens, at \$2.50 each.

M. ISBELLI, Norwich, N. Y.

I have 5 hybrid queens, ready April 15. Price 45c each. W. C. WRIGHT, Reagan, Falls Co., Tex.

I have a few first-class queens from a pure mother, reared last autumn, that produces hybrids, which I will sell for 75 cts. each, and guarantee safe arrival. OSCAR F. BLEDSOE, Grenada, Miss.

We have four hybrid queens to dispose of by the 20th of April, at 60c each; also some black queens by May 1, at 35c each. No discount on quantities. KENNEDY & LEAHY, Higginsville, Mo.

I have six good hybrid queens to be removed about June 1. If any of the friends want them I will ship them about that time at 60c each, safe delivery guaranteed.

D. O. WAKEFIELD, Waverly, Lan. Co., Neb.

CAN BEES BE MADE TO HIBERNATE?

HOW MUCH COLD, AND HOW LONG, WILL BEES
STAND IT AND NOT FREEZE?

AMONG my earliest recollections I remember of going through a piece of woodland at the close of a sunshiny day in March, and there finding dead bees (as I supposed) on the snow. A kind of pity came over me for the poor little things, so I picked one up and looked at it, when a new thought came over me, which was that I would carry some of them home and show them to father, as he had been a keeper of bees, although he had none at this time. It so happened that I had a small box in my vest pocket, and in thinking how I could carry them home I brought into requisition this box. After putting 15 or 20 of the dead bees in the box I put on the cover and slipped it in my pocket, not thinking of it again until all were gathered around the fireside at night. I now thought of it, telling father how I had picked up the dead bees in the woods; and upon taking the box from my pocket we were all greatly astonished to hear a loud humming, with much commotion going on inside; for the warmth of my body had brought my dead bees to life. Father said he believed he had heard of bees being chilled and afterward reviving when the sun warmed them up, and proposed that I feed them some honey, which we chanced to have in the house. That night, boy fashion, I planned out how I could get a swarm of bees out of those dead bees on the snow, for there was a lot of them.

The next morning, much to my sorrow I found it raining when I awoke. This rain, I thought, would surely spoil my bees in the woods, and my vision of

a swarm of bees began to look dim to what it did the night before. About 10 A. M. it stopped raining, and I started out with a box for the bees, although I hardly expected I could revive the wet dead things. Arriving where they were I took one in my hand and breathed on it a few times, when, to my great satisfaction, it began to move. I now picked up my box full, leaving a few still on the snow. These all revived, and were put with the rest. The next day I chanced that way again, and tried to revive some of those left on the snow, but failed entirely, although I carried quite a number in my pocket all day. The weather had been freezing cold for six or eight hours before my last trial, and I laid it to this, why I could not revive the last.

I could tell the juveniles how I fed them, and worked for my bees to grow into a swarm, until one by one they died; and how a neighbor found a bee-tree near where I found those bees, if such were the object of this article; but as the heading will show, I started out to tell you something regarding the hibernation of bees; and the reason I spoke of this incident at all was that these chilled bees which I picked up were hibernating more really than those of friend Clarke have been during the past winter, fixed upon his "tree-trunk" principle.

Time passed on, and I became the possessor of not only one colony of bees (as I so desired to in those early days), but of so many I could count them by scores. During the past 16 years I have many times revived chilled bees, but could never revive a bee after it had been frozen, although friend Root tells us on page 127 they can be revived after being exposed to a zero temperature, or something of like import. I have read somewhere that as soon as the juice inside the bee becomes frozen, the

tissues of the different organs would be ruptured, which necessarily would cause death; and all of my experience proves the writer to be correct, although some claim to have revived frozen bees. Only yesterday I caused fourteen healthy bees to be chilled on the snow in a temperature of 40°. As soon as chilled, seven were taken to the cellar, where the same temperature would be continued, while the other seven were left on the snow all night, the mercury standing at 8° below freezing this morning outside. Upon bringing those from the cellar, where it was warm, they began to breathe in less than three minutes, while the seven, brought from the snow at the same time, and put beside those from the cellar, showed no signs of life after being warmed one half-hour. Hence I concluded that, as soon as a bee freezes, it is dead past revival.

Well, friends, you can call the above a rambling preface, for I have now just got to what I started to speak of.

Some four or five years ago Prof. J. F. Boynton, the noted scientist who exposed the Cardiff-giant fraud, became interested in bees. After keeping bees a year or so he came to visit me; and in our bee-talk he said that he was going to institute a new plan of wintering bees. Upon asking him what the plan was, he said that he had ascertained that, if bees flew out of the hive when the temperature was at 46°, they could be revived after becoming apparently lifeless for 48 hours, and he was sure that, if an even temperature of 46° could be kept up, that 48 days or longer could be passed as safely as a shorter time. I told him that I thought he was wrong; but, for the moment admitting the correctness of the thing, asked how he was going to get a whole colony into the hibernating state. He said he could do it; but as I would not believe his first proposition he would not explain the last. He also said he would prove that his ideas were correct, during the next winter, and give the bee-keepers of the world a plan whereby they could winter bees every time, and that without the consumption of a pound of honey. That fall he was called from his home, and I have not heard from him since, except that his bees all died through their not being cared for.

When friend Clarke gave out his hibernation theory I fell to thinking of Prof. Boynton's plan, and tried it twice the past winter as far as individual bees were concerned. Twelve bees were chilled and placed in the cellar, where the temperature was 42°. Every twelve hours one was brought to the fire and warmed. After the fifth bee was revived, or more than 60 hours had elapsed, no more could be brought to life; also it took a little longer each time to revive them. The first revived in about three minutes; the second in about four minutes, etc., while it took nearly ten minutes to revive the fifth one. In this, friend Root will find something a little more definite than he gave on page 127. It occurred to me yesterday, that, if the bees which were to be chilled were first allowed to fill themselves with honey, perhaps Prof. Boynton's theory might work, so I shall make one more trial of it.

If, after reading this, any one can see how the thing can be done, let him go to work till a sure, non-consuming, hibernating plan of wintering bees is brought about, which shall bless future generations, and take from this generation our present lottery plan, with all its anxious thought.

16—G. M. DOOLITTLE, 40—80.

Borodino, N. Y., April 2, 1885.

Now look 'e here, old friend; even if a bee is killed as soon as the juices of his body are frozen, I am not quite ready to give up that a zero temperature for a little while kills him. A few winters ago I was astonished to find that cocoons hanging to apple-trees contained a liquid not frozen, even during severe wintry weather. As soon as the insect was cut open, however, it froze instantly. These cocoons were in a hibernating state on the fruit-trees. There they hung on the twigs, while it was zero weather day after day, and yet it seemed as if they *could not* be frozen solid unless you mashed the life out of them. We know that frogs, fish, snakes, and other reptiles, freeze up and thaw out; but, are they frozen solid clear into their vitals? I wish somebody could tell us. I did not know how hard freezing a bee would bear and come to life, and I did not know how long he could stand any kind of freezing; but since you have given us the result of your experiments, I think I know more than I did before. This question is interesting, because there have been inquiries several times in regard to how low a temperature we must expose honey-combs to freeze out the eggs and larvæ of the bee-moth. Can Prof. Cook tell us any thing about the way in which the larvæ and cocoons of insects bear zero temperatures without injury? Do they keep warm inside, or do they freeze up solid, and thaw out again? Somebody has said that the sap in trees is in a liquid state, even when every thing else is frozen up solid; but as soon as a twig is crushed, the juices freeze immediately. I am pretty sure this is not so, but there may be a good deal of truth in it. Henderson said a while ago we should plant our early peas very thick, because they *keep each other warm*. How much do we know, and how much do we not know?

D. A. JONES'S BROOD-FRAME.

ITS SUCCESS IN CANADA.

ON page 155 we gave a description of this frame, giving dimensions, etc. Below, we give an engraving of the frame. As the dimensions were given on page 156, we need not repeat them here. It seems to me a little strange that a deep frame like this should find so much favor in Canada, when our bee-keepers of the United States so universally decide in favor of the shallow L. frame. It can not be altogether on account of difference in climate, because we have many successful bee-keepers in localities as cold as it is in Canada. We shall have to explain it, I presume, on the ground of honest differences in opinion, or because our Canadian friends have got used to this kind of frames. It seems to me it would be an excellent thing for our friend Jones to come back to the L. frame, but I presume he thinks it would be excellent to have us adopt *his* frame. There is this we shall have to admit, that our Canadian friends as honey-producers rank fairly with almost any in any country on the face of the

globe. California gets ahead a little, when they have a booming season, but I do not believe she does much, year after year.

ANOTHER CHAPTER IN REGARD TO SAYING THINGS WERE NOT THERE.

LEARNING HOW TO DO BUSINESS SO AS TO AVOID MISTAKES AND MISUNDERSTANDINGS.

MR. ROOT:—You sent me only fifty wooden-corner frames. You owe me fifty frames. I put frames together to-day, and found out you had sent only 59 instead of 100 frames. I hope you will make things all right. The other things are all right. I am pleased with them. A. B. OZLER.

Greenspring, Pa., March 12, 1885.

I do not know any other remedy for these troubles than to keep this department standing until the friends learn by these illustrations how to be careful in opening goods. With the above letter our friend incloses also a caution sheet on colored paper. This caution label reads as follows:

Caution!—When unpacking goods in this package, please be very careful not to throw out any piece with the straw. In many cases where goods have been reported short, missing articles have been found in the straw. Also look in all the boxes; for we often crowd small articles inside of others.

The matter was traced up as usual, and our head packer was the one who put them up, so we wrote to our friend that he must be mistaken. Well, here is the reply:

Your letter is this evening received. I have found the frames. I will tell you how it happened that I made the mistake. I was putting the frames together in the evening, and one lot was carried to the cellar, and I did not find them till to-day. My wife sent me to the cellar to get a bucket of coal, and I found the frames there, and they are all right. A. B. OZLER.

Greenspring, Pa., March 20, 1885.

Now to be brief. Within the past few days we have received the following letters:

Well, Laura, you were right about those other 20 rabbits wrapped up in printed paper. There were 3 bunches of 20 each in the box of tin separators for the wide frames, and 3 bunches of 20 each in one of the big crates, making the 120 in all, correct. Now for the "wherefore." Eight of the hives I got were for my brother; he lives $\frac{1}{2}$ mile closer to town than I, and when we got home with the goods he said he would take off from the wagon one of the big crates, and so we did; but after a few days he hired me to set up his hives (and, as I said before, one of the crates was broken, so he took that one), so I went after the crate; but before I got there he took out one bundle of the rabbits and never said a word to me about them until after the other 20 came, then he could say there were 20 down at his house, and he knew all the time I was short 20. Brother R., don't accuse your clerk for not putting up the goods right, for he did his work all O. K. It was my brother that caused all of the trouble.

Coal Vale, Kan., Mar. 31, 1885.

S. C. F.

In the above case you will notice that the goods had been unpacked and "carted around" quite a little before our friend complained. And then he did not scruple to say positively that the things were not there.

A few days ago one of our boys came to me, saying a lot of pocket-knives were missing in a valuable shipment. I asked him to tell me the circumstances, and he said he opened the box out in the shed, and somebody called him away. After a while he went back and finished checking them off, and he found so many were not sent. I asked him how he knew somebody did not steal four or five boxes. He said he did not *know* positively, but he did not believe they did. I told him I should never dare to send any claim to a manufacturer when goods had been unpacked in that shape; that valuable goods especially should under no circumstances be unpacked in the "shed." I told him to bring the whole of the goods into the store. He made excuse, that they were "awful heavy." To be sure, they were heavy, for there were several hundred dollars' worth of valuable pocket-knives. When he had got the box into the store on a clean counter, I told him to pile up the packages four wide, five long, and five high. This would make just the number there ought to be, and there could not be any mistake or miscount, for any one could see at a glance, if there was not a complete and square pile. You see, we made the goods prove themselves. And you can often do this, friends, when the goods will pile up so that, by multiplying, the precise quantity is known at a glance. After they had done as I said (and it really required much less time than to count the packages, 1, 2, 3, 4, to see if the goods are all there) they drew a long breath of relief.

Here are some friends who declared their goods never reached them. We sent a tracer; and the express company, after considerable trouble, returned us the papers proving that the goods had been delivered long ago. We asked what it meant, and here is their reply:

Upon receipt of yours of the 5th inst. we were as much puzzled as yourself, until we made a thorough search and found the missing box, which was overlooked when received, and placed with other goods received at the same time, hence we were all the while looking for them to come.

THE H. F. MOELLER MFG. CO.

Davenport, Iowa, Mar. 9, 1885.

And still another.

This day I happened to open the box entirely that contained the envelopes you sent me, and to my surprise I found the two handkerchiefs I said you had not sent. Well, I beg pardon; I thought when I opened the boxes of goods I should be sure to find every thing there was in them, that you would not have to tell me to look the goods over again, as you have often told others to do; but I got caught this time, and every thing is all right now.

Clarksville, Tenn., Mar. 23, 1885.

A. SNYDER.

You will notice, friends, that the same caution label was inclosed with the above order also, and yet friend S. wrote us the goods were not there, when he had not even looked into his box of envelopes.

And still another.

The fork I wrote you about being missing, after looking over the straw again I found it. I hope it has not made you any trouble. C. D. DUVAL.

Spencerville, Md., Apr. 4, 1885.

And another still, who declared that we left out a package of honey-knives. See where they went to:

A friend of ours took those honey-knives out of the P. O., and then went into a restaurant and laid them down and came away and forgot them, and forgot that he ever had them in his possession, and they were lately found and delivered to us, so it reflects nothing on you. SMITH & MORGAN.

Columbus, Wis., Dec. 8, 1884.

GROWLERY.

THE CONTENTS OF BEE-JOURNALS.

EDITOR GLEANINGS:—I am in a rather complaining mood to-day, and therefore I trust that you will excuse any thing that I write, which does not exactly agree with your opinions and those of your subscribers. Several times I have laid aside bee-journals, with a feeling that I had gained nothing by reading them; but I always attributed it to my not being in the right mood to comprehend or remember just what I had read. And now, after carefully looking over some back numbers of bee-journals, I find that the subjects treated upon are not those which are most essential to the promotion of our interests; that is, in my estimation.

To be sure, it won't hurt anybody to be well posted in regard to some of these minor details; but, is it necessary and beneficial to protract controversies over "Moral and legal patents," and fill pages which should be devoted to the interests of bee-keepers with talks about rabbits, chickens, silkworms, carp, and carp-ponds, and all of these little matters for which I think the majority of bee-keepers care nothing, or, if they do have any interest in these things, would prefer to purchase books or journals treating those topics and nothing else? I for one shall be glad to see the time when the more important subjects of our occupation are brought to the front and *properly* discussed—not by trying to ridicule or cast aside the opinions of our neighbors, but let each interested bee-master give in his opinion and testimony, regardless of what others have written; and when the subject has been fully discussed, let the editor make a concise summing-up of the different testimonies and ideas, and give his subscribers the benefit of his decision. Would not this manner of dealing with subjects do away with a great deal of this going over and over the same ground which perhaps was discussed two or three months before? for then one could turn back, and, by just glancing at this summary, know just what had been written and what omitted.

During the discussions about the sizes of section boxes, and brood-chambers, and the clipping of queens' wings, also in regard to the reversible frame and the "Heddon supplies," I for one could not tell what the opinions of the bee-keepers nor the editors were without beginning at the start and re-reading all that was written in regard to them; and I sometimes thought that some of those who did write had no definite idea of what they were writing about. I suppose you think this article belongs in the Growlery; but as you have that heading in your journal, perhaps you wish to see it well patronized.

C. H. SMITH.

Pittsfield, Mass., March 24, 1885.

Friend S., your remarks are good, and I

agree with the most of them. But, here we are again, with your letter in print; and yet, if you will excuse me, is there any thing in it very practical or helpful in the *care of bees*? If you want my opinion, I should say, first, I am a little afraid you are in a complaining mood. I have already hurt one brother's feelings, I fear, by declining to publish any more, just now, on moral and legal patents. In deciding what shall appear in GLEANINGS, and what shall not, I believe my sole motive is to serve our readers best, and we have had a host of pleasant letters in regard to what has been said on rabbits, chickens, silkworms, carp, and carp-ponds. Even if we are bee-keepers, I believe the general feeling is that we want to look over the fence occasionally, and see what is going on in the world. I should be very glad indeed to be able to make a wise summing-up of the evidence brought forward in regard to the things you mention; but my experience, judgment, and wisdom, are not equal to the task. The size of section boxes, for instance, I believe we are safe in saying, 4½ square is pretty generally agreed upon; but when it comes to how wide they should be, this involves separators or no separators, and we want the result of more experiments before I should dare to say the point was even *tolerably* well settled. I believe the *general* opinion is, that we do not want queens' wings clipped, but I am almost afraid to say so. In regard to reversible frames, I am satisfied with the one I have given you, but the matter is a good deal a sea of conjecture and indecision as yet. Heddon's supplies, I think, we may sum up as a pretty good thing; but much will depend upon the reports at the end of this coming season. It takes a long while, friend S., to settle decisively these disputed points. A great many of us have decided, so far as *we* are concerned. You will notice in this number that friend Heddon is satisfied in regard to the wintering problem; now, it will probably be a long while before we all agree with *him*, or, in fact, before we *all* agree on a great many other matters.

BAD REPORT FROM HONEY-DEW.

MY losses up to date are two colonies, with indications of one or two more to follow, caused by honey-dew, or its right name, "bug-juice," and as there have been no losses reported in GLEANINGS from others, can it be that ours was of a more inferior quality, as none could be worse, and more deceiving to look at on the outside? Hop honey, I think, would be as good a name to give it, for some of my customers told me that if I could not feed my bees any thing better than hops, they wanted no more of it put up in that shape; for I must confess I sold what looked to be A No. 1 quality of honey that was some of this hop-apis bug-juice, honey-dew honey, that made our pets go wild the past season. The colonies that are affected had stores from it, and those that appear all right have some stores from the season of 1883, this being saved on account of so much apple-bloom last spring, and so the bug-juice, or hop honey, was stored in boxes.

C. L. HILL.

Dennison, Ohio, March 9, 1885.

BEE CULTURE IN FLORIDA.

SOMETHING ABOUT REVERSIBLE FRAMES; HOW IT WORKS IN PRACTICE.

AS I could find no cure for the Florida fever but to partake of the climate, etc., I came here the 12th of Jan., 1885, and it is truly wonderful to witness the change from Maine here. I can hardly believe it is below zero, while here it is summer. Only think of oranges fully ripe on the trees, and bloom now in full, and one of the most delicious perfumes float in the gentle breezes from the blossoms. Trees are putting on a new growth, birds are happy, and so are all the people. We often hear shouts of joy far away in the open pines.

I came here undecided as to a home, but I have fully come here to stay. Of course, there are things we must be denied, but we enjoy much that we can not in a cold climate. Nearly the first thing I did was to look into the bee-works. I found them at work, strange to say, working lively; and on looking into hives I found them strong in brood, and some new honey and comb produced. Yes, in January. I could not find any one who was up to the times in improvements, to get actual facts from; but all agreed that bees did well. Bees are all in box hives or large frame hives, two feet long, and frames 12 inches square, with nothing but a cleated board for cover. If they warp or shrink, so bees creep in, and a wholesale robbery is the result, they get no careful attention. These hives are supposed to be for extracted honey; but, give me a regular L. frame, and a hive that can be controlled every way. The hives have no division-boards, so a light colony stands a poor chance to guard against ants and robbers, as well as being obliged to warm the large open spaces, and cold air that creeps in all around the cover.

I went to see a man who keeps quite a number of colonies, but I was obliged to borrow a large net to protect myself from the bees. I found no one at home; but he came soon, and, to my great surprise, he fed the bees in a large sheet of shells, and also went around and slopped some sugar and water right on to the bees, by lifting the cover and turning it out on the frames. I told him I would not do it for any thing, for it must make more mischief than good, for the syrup ran right out of the front of the hives, and, of course, there would be a general fight and uproar, which there was. I never saw such a cross lot of bees; even the gentle Italians came at me, about as a little boy would at his mamma, after she had given him a bit of sugar, as if to say, "I'll have more." I never could think of opening a hive where bees had been fed in this way, for, oh how some one would be overrun with the robbers! This was in the early part of the day, so a long day would lay out many a would-be good colony, or, at least, lay a foundation for such.

Another man who had seen me transfer a colony thought he would do so with one of his, so he rigged a hive as he thought best, and one morning did the job right on the old stand, and I happened along soon after, when they told me they guessed their bees were fighting. Then I saw what they had done—transferred out of doors, in a very warm day; and as he knew nothing of the effect of honey being where bees could get a free taste, they had got the best of the colony. I told him never to allow a drop of honey or sweets where bees could

get it in the day time. I was afraid he would lose his bees, and so he did. They were robbed, and queen killed, and finally they left and came over into one of my hives, right among the bees. I smoked and united them; and as soon as I found where they came from I paid for them.

I have ten colonies. I do all my transferring in a building; and as I have been on a jump ever since I came here, I do such jobs in the evening, then by morning the honey is all cleaned up, and no excitement follows. I regulate the entrance-blocks and division-board, according to the colony. I have made long days; have done considerable in the orange-groves, and other work, and have been making hives. I have a few sections partly capped now; they are over some frames that I reversed, and I do believe when we reverse them in just the right time that it is one of the greatest improvements ever made, to say nothing of full combs. I think we shall drive the bees into the boxes; at least, it works so with me. I always have the combs down to the frame, and close them up to not more than $\frac{1}{2}$ inch; I think the closer they are, the better the bees work in the boxes, for they have not much room to bulge the honey in the frames; and, too, it seems more to the queen like her own home.

We have here some difficulties to meet that are not in a colder climate. The ants are quite bad, but I believe there is a remedy for all troubles, and I will give mine. To make it cheap and light, I strip up barrel-staves about $1\frac{1}{2}$ inches for large hives, to 1 inch for nuclei. I nail two on front of nuclei and two on back, in a Δ shape, some like a sawhorse, so as to set in old fruit-cans of water. On the large hives I nail on each corner; I allow about 10 inches of legs below the hives, and I find, too, these dishes make an excellent watering-place for the bees, and, by the way, a hive 10 inches high works much easier for me. I also heat quart cans and unsolder them and straighten out; these I nailed under front end of hive, and bend down a little to make an extended alighting-board for bees, all of which works in practice as well as in theory. Shade for hives in many places we can not have. Natural shade I make in this way: Get out slats 4 feet long; cut out a notch near one end. Now sharpen the other; cut open the seam of old bran-sacks, and bind the corners to the four ends of stakes, and you have a shade that you can fix just as you want; and when you work on a hive, just pull up the two on one side, and stand them on the other side of hive. The sticks can be varied so as to shade the entrance and any part of the hive, and bees will work with it, when they will lie idle if not used. Try it, some one; it is not patented. This all may look like work and care; but, how do we accomplish any thing without such? For want of shade, and where ants have the run, many light and heavy colonies have deserted their hives. E. P. CHURCHILL.

Tampa, Fla., March 21, 1885.

I know, friend C., there are many pleasant things about Florida; but at the close of your letter you have suggested some of the unpleasant ones. After my visit in the South, I came home with more of a disposition to thank God for our frosts and snows than ever before. Yes, I think I can thank him even for our unseasonable zero weather; for these same apparent drawbacks have been a large factor in making our Northern

countries what they are. If we raise plants in the greenhouse, they have got to be hardened off, as gardeners term it, before they are fit to go outdoors, and I fear you will find, after you have stayed in Florida a few years, you will begin to suffer for the lack of the "hardening-off" process.

POLLEN, AND ITS RELATION TO BROOD-REARING.

PROF. COOK GIVES US SOMETHING VALUABLE, THAT HAS A DIRECT BEARING ON THIS MATTER OF WINTERING BEES.

EDITOR GLEANINGS:—You and the readers of GLEANINGS will remember that, in a paper sent by me to last GLEANINGS, I said that bees sent me by Mr. Doolittle, dead, as he said, of diarrhoea, showed no pollen in their intestines, but were characterized by the usual odor of diarrhoea, and the feces showed the bacteria which I find in all fecal matter from bees which are suffering or have died of this disease. This is the only case where I have found bees dead or suffering from diarrhoea, that had no pollen in their intestines. I said in that paper that there must have been nitrogen in their food, else we would not have found the bacteria and the putrescent odor. Since writing said article, Mr. Doolittle has written me that the bees were given clean combs in September last, fed wholly on sugar syrup, and reared brood in the winter. He also states that he fed the syrup in small quantities, taking some time to do it, instead of feeding all at once, and that his other bees gathered pollen in autumn—October, I think—but these, he thought, did not gather any.

Since I wrote the other article, Mr. Doolittle has sent me a small piece of the comb from the hive, and I find under honey—I suppose syrup—quite an amount of pollen, so that its presence was easily demonstrated by use of the microscope. Now, the fact of breeding makes the case clear. Bees *can not rear* brood, which always contains nitrogen in the tissues, without nitrogen in the food; but pure sugar syrup contains not a particle of nitrogen. This, then, is further proof that nitrogen was present, and the bees could and did eat it.

Again, to make assurance doubly sure, I took all the fecal matter I could collect from the bees not showing pollen, and carried it to Dr. R. C. Kedzie (our chemist, and a very able one), asking him if it contained nitrogen; and if so, whether the amount was considerable. Here is his reply:

Prof. A. J. Cook:—The material you placed in the hands of the Chemical Department, labeled "Bees-Feces," has been submitted to qualitative chemical analysis, and was found to contain combined nitrogen in abundance. When the material was rubbed up with soda-lime, and heated in a test-tube, ammonia was given off abundantly, as was shown by the odor, and by the blue color instantly imparted to the blue litmus-paper when held in the mouth of the test-tube. I inclose samples of blue paper. There was not enough of the material for quantitative determination. R. C. KEDZIE.

Agricultural College, March 26, 1885.
We see, then, that the bees did have access, and did eat pollen or some similar substance.

Is it not possible—aye, probable—that the bees gathered pollen, or possibly meal, in the fall? Surely the method of feeding, as it would stimulate the breeding impulse, would incite the bees to gather such food. It would have been far better to have fed all syrup at once, and then not to have left the

matter of gathering pollen to a guess. This vitiates and renders doubtful the force of the experiment.

It is hard to say just why the bees had no pollen-husks in the intestines, though it will be remembered that some did. Is it not possible—nay, probable—that such bees ate the jelly, or chyme, prepared for the young bees? Quite possibly they ate up the brood. In either case they would get the nitrogen, and not show any pollen husks or grains in their intestines. Eating meal, too, might account for the nitrogen, and the absence of pollen grains or husks.

The present terribly severe winter must enforce the following points:

Good cellars, and not chaff hives or packing, are the sure conservatories for our bees in winter. They are always economical, and, with proper pains as to food, safe.

Good sugar syrup, or non-nitrogenous food, is much the safest for bees in winter.

Bees, even though fed on pure carbo-hydrates, are not proof against severe cold—they may freeze—with no show of diarrhoea.

Azoturia, which Williams, one of the best authorities, calls a hyper-nitrogenous condition of the system, is a very serious disease which often attacks and destroys horses and other higher animals, consequent upon a diet too rich in nitrogen. Is it not likely that our bees die of azoturia? Cold stimulates them to eat the hearty nitrogenous food which otherwise they might not eat at all. In this case, retention of the feces makes the danger greater.

A. J. COOK.

Agricultural College, Mich., Mar. 23, 1885.

Many thanks, friend C., for the valuable facts you furnish us. You will remember, that in my reply to Doolittle, on page 32, last issue, I suggested that perhaps a little pollen might be found in those five empty combs. As I was well aware, that bees often fill a cell partly with pollen, and fill it out with honey, I supposed friend D. had been careful to look out for them. If the combs are new, such cells may be readily detected by looking toward the light through the comb.—Now, friend C., in regard to cellar wintering in place of chaff hives, do you not need to qualify this advice so as to meet different localities? Perhaps it would take more of the sugar to do it; but with our changeable climate, I am hardly ready yet to advise cellar wintering.

REVERSING FRAMES BY AN ARM PIVOTED TO THE END-BAR.

THE ORIGINAL INVENTOR OF THE HOWES AND HEDDON ARRANGEMENT.

ISEE in GLEANINGS that friend Howes thinks that Mr. Heddon, and no doubt all others that use the pivoting arrangement for reversible frames, are infringing on his invention. Will you please tell Bro. Howes, that, while he may be an original inventor, I used this same pivoting arrangement more than ten years ago, for the same purpose?

You remember, that about the year 1870 Mr. J. M. Price, of Buffalo Grove, Iowa, had a great deal to say about his revolvable-reversible double-acting bee-hive, with which he could produce such extra hardy and prolific queens, which to me was both

amusing and instructive. From him I got the idea of the probable advantages of a reversible frame. In April, 1872, I sold out in Iowa, and came to California, and lived near Lathrop that summer; but during the summer of 1873 and 1874 I lived on the west side of the Great San Joaquin River. I then had about 60 colonies of bees; and as the earliest and best honey was made in mountains, I took them up into the Hospital canyon during the months of February and March, and set them near the house of my respected co-laborer, G. W. Hoxie, who also had a few bees; then in June I would take them back to the river again.

Well, my management, which was altogether new to Mr. Hoxie, soon aroused his enthusiasm for bees, and he was soon ready to try any and every kind of experiment with me, and among them was the reversible frame, instead of the hive, as Mr. Price had done. Our first plan was to fasten a heavy wire to the end bar of the frame, with staples, precisely as described in GLEANINGS, 1884, page 155, and then bend one end back under the bottom-bar, and the other straight out for a supporting-arm. But as this was too unsteady, and, if they filled one side with honey and not the other, it would pull it out of true, we soon abandoned it. We then tried strap iron an inch wide, fastened in the center of the end-bar, just as described on page 156 of same number of GLEANINGS, and bent it out at the top of the frame, just as we did the wire for a frame-support. This did better; but as the frame would sometimes tip when top heavy, we punched a hole through the strap iron, about an inch from the top, and drove a small headless nail through this hole in the end of the frame, which held it true while in the hive. When the frame was lifted out, the strap iron had spring enough to slip off this headless nail, and then turned down, and slipped over the nail at the other end, which reversed your frame, and was then ready for the hive again.

This all worked nicely, and the way it would cause the queens to breed was astonishing; but pretty soon they would commence sticking glue between the strap iron and the end of the frame, and oh what a time we would have to clean off the propolis! But as honey was cheap, and labor high, as I remarked on page 162, present Vol., we abandoned it, although I still have several hives with reversible frames, but of a different style.

Mr. Heddon is the only man I have seen who gave the true effect of reversing the frame, so far as the brood-nest is concerned; viz., in the spring, when the queen is enlarging her brood-nest, it facilitates it rapidly; but when they are crowding her with honey, it diminishes it just as rapidly, for they don't seem to want to take the honey out from below the brood; and just as fast as the young bees hatch out at the top they fill it with honey.

Now, friend Root, if you or any of your readers have any doubt as to what I have written, they can write, inclosing stamps, to the Rev. Geo. W. Hoxie, Applegate, Josephine Co., Oregon. J. F. FLORY.
Lemore, Tulare Co., Cal.

Friend F., a great many of us remember J. M. Price's revolvable-reversible bee-hive; and I felt pretty certain when Mr. Howes claimed to be the first to use such an arrangement, something would come up to show he was mistaken. No one doubts your veracity, friend F. You have been too long before the bee-keeping fraternity.

MORE ABOUT THE MANUFACTURED COMB HONEY.

MORE DEVELOPMENTS, SINCE OUR ARTICLE ON P. 238 WAS PUT IN TYPE.

THE *Grocer's Criterion*, of Chicago, under date of March 16, has an article headed, "When will Humbugging Cease?" and makes a rebash of the article we give from the *Philadelphia Times*, p. 238. The *Grocer's Price Current* of March 14 also contains the following editorial:

Three glass boxes of fine comb honey were on exhibition in a wholesale grocery, Monday. "That is very fine as far as looks go," said the proprietor, "but we only have it on exhibition. It merely represents Yankee skill. That comb and that honey never saw bees. They were manufactured by human hands. The comb is made of paraffine, or beeswax; and the honey, which is also false, is blown in by machinery. We have another kind of honey, which is put up in glass cups, with a small piece of comb in the center. This honey is generally made from cane sugar, glucose, or syrup."

It is the old story over again, and these grocers' papers ought to be ashamed of themselves. This last item quoted is abominable. Before I can believe that any wholesale grocer ever had any such honey on exhibition, or ever made any such speech, I should want the name and place, so that the man can be hunted out, and the matter proven beyond question. If it is really true, that the whole thing is not a complete falsehood, made by some reporter who wanted to get up a sensation, I should say that the proprietor himself was deceived—that he had got some genuine honey that somebody persuaded him to believe was manufactured. It has never been done, and can not be done. Do our grocers' papers delight in having the world believe that every thing is a fraud? Are they judging honey-dealers and honey-producers by the way the grocery business is carried on? I am informed that an item has just come out, giving the name of a butcher-shop in Philadelphia where dog meat was sold as veal. Suppose we come out and declare there is no real veal—it is all dog meat. These stories about the adulteration of honey and other commodities, in spite of all our bee-journals can do, such as have been quoted, are almost as unreasonable and inconsistent; and in spite of all our bee-journals can do, these editorials about comb honey being made of paraffine and glucose by Yankee ingenuity will probably be copied from paper to paper, persuading men that the world is all corrupt, all after the almighty dollar, that true religion and true Christianity are extinct, and that we are all going to the "dogs."

MANUFACTURED COMB HONEY; STILL MORE ABOUT IT.

Jan. 5th I received a letter from my brother, who lives in Denver, Col. (he used to be in the grocery business, so he handled honey some). In this letter he writes about the fine California honey he has just been buying. He says, "We can always be sure that honey which comes from California is pure, as they have nothing cheaper to adulterate it with, while honey which comes from Chicago you can be pretty certain is adulterated with glucose. A gen-

tleman told me that he saw them make comb honey in Chicago that did not have a particle of genuine honey in it, as they made it comb and all." Now, I do not believe a word of it; but, why did this man say so? and why are the people of the West given to understand that the honey of the East is made and adulterated? I can see no reason for it, unless that it is done by men of California (not bee-men, but honey-dealers) to exclude eastern honey, and make a market for California honey. When I received this letter I thought I would write and tell you of it, but I put it off, and probably would not, if I had not seen in last GLEANINGS where Joseph H. Snyder asks the question, "Can honey-comb be counterfeited?" and you say it is a falsehood of the papers. By what I have written, you can see that it is not told by the papers alone, but by men whose interest it is to make people believe that our honey is not as pure as California honey.

Warwick, N. Y.

H. P. DEMAREST.

Friend D., hunt up the gentleman, make him tell him where he saw them manufacturing comb honey in Chicago, and go there and hunt them up. If it transpires, however, that the gentleman whom you mention is found to be a man whose word can not be relied on, it were a pity you hadn't found it out before you sent us this letter. I do not know what does possess people to pass around falsehoods in this way, unless it is their desire to make believe they are better posted than other people.

I clip the following from a Kansas paper. I think that that caps any thing I have seen lately. I think we ought to clip in and help him out with a large "ad."

FRANK D. FRENCH.

Miller's Corners, N. Y., March 11, 1885.

Below is the clipping inclosed with the letter:

"Can make honey that can not be distinguished from pure honey, for eight cents per pound. Send fifty cents in postage stamps for recipe. Address box 4, Wakefield, Neb.

Thank you, friend F. Send us all such notices you can possibly get hold of. As good liquid honey can be bought now almost anywhere for 10 cts. per lb., it seems to me there is not very much of a temptation to manufacture spurious honey. Set down any man as a humbug and swindler who wants to sell a *recipe* for doing something. All recipes of any value are sooner or later found in our recipe-books, or in the industrial papers devoted to that particular class to which the recipe belongs. Fifty cents, or any other sum, for information that can be printed on a little slip of paper, is a swindle.

DO BEE KEEPERS ADULTERATE THEIR HONEY?

This is a question which we should consider very carefully. Bee-keepers should be careful how they follow the advice of Mr. Heddon and Mr. Doolittle and others, in regard to feeding sugar syrup. We should have to go to some old-fogy log-gum bee-keeper to get pure honey, if we should follow their advice. They make a terrible fuss when some one says we sell them sugar. But, what are *they* doing? Are they advancing the sale of pure honey? Not much. Just as long as they feed sugar to their bees they will sell adulterated honey.

Platteville, Wis.

P. H. FELLOWS.

Friend F., I think you are borrowing

trouble unnecessarily. If anybody says that we feed sugar to the bees in order that we may make honey of it, because sugar is fed in the fall for winter stores, I should say such a person would have to talk. The superiority of pure sugar for winter stores over even the best of honey is now so well agreed upon, that it is without question going to be the staple winter stores of the future. If bees are properly fed up in the fall, there will be little if any need of feeding bees in the spring; and when you hear any man talk about bee-keepers adulterating honey with sugar, ask that man to visit some apiary at a time when honey is coming in, and his eyes will soon satisfy him that it is genuine honey, gathered from the flowers, that bee-keepers put up, and nothing else. Remember, also, that it is not what bees *eat*, but what they *gather*, that determines the quality of the honey.

Here is still another, and this time it hits the maple-sugar makers instead of bee-men and grocers. Now, friends, if it is true that men who own sugar-bushes adulterate their maple sugar with cane sugars, let us get good proof, and then show them up without mercy. But I am afraid maple-sugar makers are slandered just as the bee-keepers have been. No doubt owners of sugar-bushes buy cheap sugar; but does it necessarily follow they are using it to adulterate the syrup they sell?

It is an open secret that great quantities of muscovado sugar at six to eight cents have been sold to owners of sugar-bushes, and that the yield of "pure" maple sugar will be larger than ever before. A single owner of a "sap-bush" bought ten barrels of the cheap brown sugar. Imitation butter *must* go.—*Chicago Tribune*.

WINTERING PROBLEM SETTLED.

OR AT LEAST FRIEND HEDDON THINKS IT IS.

I HOPE no one will be startled when I say that I have solved the wintering problem, to *my own* satisfaction. When I say that, notwithstanding I have in past years been quite a heavy loser of bees during winter—bees treated by nature and myself, the same as others in other locations, which wintered well—that for the future I would not give ten cents per colony to have my bees insured against winter losses, I have, to back it up, satisfactory evidence of the correctness of the pollen theory.

One year ago last winter I made extensive experiments regarding the cause of bee-diarrhœa. The winter was such that but little diarrhœa occurred. Although every thing pointed favorably to the theory, yet I was not perfectly satisfied. Knowing that there is some truth in the theory, that all our improvements and discoveries are a slow growth, cultured by many, yet I felt that this slow growth might go on growing until after I had ceased to be, and yet be growing, with little signs of blossoming or bearing fruit. Perhaps I am a little impetuous for something in the near future—something I can profit by, here and now. If I am, this propensity led me to again go into experimenting more than before; and while last winter's experiments cost me more than \$1000, I feel more than paid in the satisfaction I now enjoy over this problem—more

than paid as regards my own future bee-keeping, to say nothing of what I may do for others; for I feel confident that I can now lay down specific rules by which all can winter their bees with *perfect safety every time*. The near future will decide whether or not I am correct. If any such rules have ever before been given us, I know not when or by whom. I am aware that many bee-keepers have supposed that the wintering problem was a simple one, and one which they understood. They thought so because they had never failed of successful wintering. Then they would tell us just how they did it, and the different means and ways reported were almost as numerous as the reporters. And then some one would arise and report failure by the same processes, which proved conclusively that the ways and means provided by the successful reporters were only such as would warrant success with their individual conditions and environments.

I now propose to lay down such rules as I fully believe *all* can succeed with; and without courting any belligerent discussions, I wish to leave my record as a discoverer in this problem, with the actual practical results of the future.

I must first give great credit to Prof. A. J. Cook, with whom I have been corresponding, and sending specimens for the past month, and who has worked out the chemical and microscopic part of the problem in a large degree.

First, having been able to remove the cause of bee-diarrhœa, and, of course, its consequent effects, I have found that bees quite readily succumb to freezing, which I believe is greatly aided by their inability to expel aqueous vapor in a low temperature. By unwarranted and severe exposure to cold, I have frozen to death over 75 colonies, with no diarrhœa whatever. Had I not first removed the cause of diarrhœa, these colonies would have discharged that fecal mass before they succumbed to cold (as we commonly use the term).

Second, this fecal discharge known as bee-diarrhœa is every time composed of nitrogen, as I have been claiming for the last two years; and while, undoubtedly, in 99 cases out of every 100, this nitrogen is taken from bee-bread or floating pollen in the honey, Prof. Cook thinks that *possibly* it may be taken by consumption of bacteria by the bees, which he has found in rare cases swarming in their intestines. We would find bacteria with fermentation. One fall my bees carried in nearly a quart of cider per hive. Though the following winter was not severe, yet those that were confined for three or four weeks showed no symptoms of fecal accumulations at the end of that time. I have seen colonies have diarrhœa badly, with no longer confinement with stores of ripe honey and perfect bee-bread. I have also seen the same fecal accumulations take place with only two or three days' confinement, but at that season of the year when bees were exerting themselves, and consequently consuming pollen daily.

I have just read Mr. Doolittle's article on page 231, and in the *Am. Bee Journal* I read his account of the time and way in which he supplied the colony in question with sugar syrup and no pollen. Scientists know there is no nitrogen in pure sugar syrup. They also know that tissue can not be created, either in the growth of new individuals, or in making up waste, caused by exertion in older ones, without the element nitrogen.

The 200 young light-colored bees, together with

the "patch of brood as big as a silver dollar," show conclusively that Mr. D.'s colony possessed nitrogen, and it seems clear to me that they possessed pollen; for Prof. Cook writes me that, in examining bees and combs from this same colony, he found traces of pollen in the comb, some cases of undigested pollen in the bees' excreta, also bacteria; and later he writes me that Dr. Kedzie, our State chemist, finds this excreta from Mr. Doolittle's bees "containing nitrogen in abundance." Prof. Cook also says that Mr. Doolittle's case appears to him to show very mild symptoms of the disease. I had one colony die with the disease in most radical form over a month ago, from which I sent Prof. Cook diarrhœtic excreta from a top-bar, and pollen from the comb just under the top-bar. He analyzed both carefully with a powerful microscope. He says the excreta was not only almost entirely pollen, but the *same kind* of pollen as that sent him in the comb beneath the top-bar. He concludes by saying, "The pollen you sent had been liberally appropriated by the bees, whose excreta you sent." The Professor also says, that, after many examinations, he is positive that bees never discharge dry excreta. He further writes me that he procured some bees of a neighbor. These bees were lately dead of diarrhœa, and he found their bodies nearly bursting with the dark turbid excreta which, when microscopically examined, proved to be pollen grains held in a watery mixture.

I assert the following, without fear that future discoveries will prove me incorrect:

1. Diarrhœtic accumulations are composed of nitrogen.

2. This nitrogen is practically, and in nearly every instance, taken by way of consumption of bee-bread, or floating pollen, in the honey.

3. Bees can use bee-bread for making chyme, or jelly, for larval food, without getting it into their intestines, thus aggregating fecal matter. But said chyme, being fed to the larvæ, and not consumed by the old bees, they can and do breed in confinement, without accumulating fecal matter, thus engendering disease.

4. Bees may quite easily perish from cold, without any disease whatever.

5. Sugar syrup contains no nitrogen, but more heat-producing elements than honey, hence it is cheaper and safer as a winter food.

6. A low temperature will cause bees to endeavor to add to their methods of producing heat, by way of food, that of exercise, and this exercising will cause a waste of tissue which the bees will try to replenish by consumption of nitrogen. (I find in every case, where my sugar-fed colonies were trusted with a few cells of bee-bread, and then subjected to a low temperature, they ate every particle within their reach.)

7. Bees will let their bee-bread alone as long as the temperature is high enough so that no exercise is needed.

8. Bees may be *forced* to the consumption of pollen by its presence floating in the honey, constituting their winter stores.

CONCLUSION.

If the honey is free from floating pollen, or bacteria, bees can be successfully wintered with it, if put into a repository whose temperature never goes below 40 or 45, if the colonies are well arranged for retaining their heat within their hives, bee-bread or no bee-bread.

To economize in food, and insure freedom from nitrogen, feed your colonies sugar-syrup stores with as little honey and bee-bread in the hive as possible, and place these colonies in a warm repository, and keep up the temperature to 45°, and you will never lose your bees during winter, with any length of confinement we ever experience in latitudes where bees are kept.

Having believed this three years, I have been at work developing a system of management by which we can get nearly all our honey stored in the surplus receptacles, bringing our brood-chamber out in fall almost entirely destitute of honey, and with very little bee-bread. I have succeeded to my satisfaction, and proven the system's advantages as regards increase of profit, and decrease of labor, in all directions, and will delineate it to your readers at a future time. It is very pleasant to be able to dictate an improved and cheaper kind of winter stores, without the troublesome, perplexing, and, in many instances, dangerous job of late extraction.

JAMES HEDDON.

Dowagiac, Mich., April 3, 1885.

MR. J. F. FLORY'S SECTION CORNER-CLAMP.

HIS REPLY TO THE QUERIES ON PP. 110 AND 162.

IN answer to your queries on pages 100 and 162, as to how I close up the ends of my corner clamped sectional honey-boxes, I will say that I am not yet satisfied *what* plan is best—to put wood in the end as you suggest, or tin, cut about $\frac{1}{2}$ an inch narrower than they are high, and $\frac{3}{4}$ inch longer than they are wide, and then bend it so it will fit close over the outside of the section, and then slip it under the clamps, which will hold it tight up to the section without nailing, or else have your clamped sections about $\frac{1}{2}$ inch shorter than your cap, and put a thin board $\frac{1}{8}$ or 3-16 thick between them and the cap. Some will use them just as they do the Tulare sectional box; viz., have them fit up snug to the side of the cap; but I object to that plan, for the simple reason that, if bits of comb are attached to the cap, in lifting them out or in lifting the cap off first, leaving the honey sitting on the hive, which is the better plan, it will bruise the outside of the comb; but by having a thin board between the cap and honey, and lifting the cap off first, these boards can be laid back, and then there will be no bruising of the honey whatever. This, of the three plans mentioned, I am inclined to think will be the best plan.

You still seem to think that I must have a *double* bee-space in tiering up. If the clamps, as you admit, are only $\frac{1}{8}$ inch thick, and you put one on top of the other, you certainly have but one space, and that just double the thickness of the clamps, making it $\frac{1}{4}$ inch, hence we can have but one space between *each tier*, no matter how many tiers you may have; while the Heddon has two and a honey-board besides.

At our last convention at Hanford, March 4, there was but one objection urged against them; and his idea was, that the bees would wax and glue between the sections. As to the wax, I have no fears whatever; but how much, if any, they will glue it I can not say, but certainly not more than the Heddon case. I am not manufacturing them, neither have I them for sale; but if any one will send me

several stamps, for postage, etc., I will mail him a sample.

J. F. FLORY.

Lemore, Tulare Co., Cal.

SWEET CORN AS A HONEY-PLANT,

ALSO SOME OF ITS OTHER—"ADVANTAGES."

A GOOD many seeds are sold, and a good deal of time and money is spent in raising plants that yield honey and nothing else. Well, dear friends, I have many times told you that I felt a little anxious when you sent for seeds producing plants that promise no return except the honey they may furnish. But if you should plant our best varieties of sweet corn, and give it a good cultivation, I should not worry about you one bit. You know we have advertised four different kinds of corn for some years past. Well, it just occurred to me this spring that perhaps I had better see if any of these old kinds had been superseded. Below is friend Kendel's reply in regard to the matter, and I thought it too bad to keep it all to myself. If you want any of the seeds he mentions in his article, he will give you the real genuine at the lowest market price; or, if more convenient, you can send the order directly to us, and we will send the things with your goods.

Mr. A. I. Root: In reply to yours of April 2, we would say we have a decided improvement over Minnesota in Ford's Early Sweet, which is nearly a week earlier, larger, and somewhat sweeter, with price same as Minnesota. For a second early, the Moore's Concord holds its own; the Crosby's is sometimes thought to be a little sweeter, but is not so fine and large an ear, so that the Concord takes the lead for market purposes. For the third, Early Mammoth has no peer; it is sweet, productive, large ear, and continues a long time in the milk. For a fourth, the Stowell Evergreen or the Egyptian are favorites, the Evergreens for evaporating; but for excellence of flavor, the Egyptian. The Evergreen is so well known it needs no description; the Egyptian is 12 to 14 rowed, fair sized ear, not quite as large as evergreen, but has a pleasant habit of producing two or three ears to the stalk when not planted too close.

You can not urge the friends too strongly to plant corn of the four different seasons all at one planting, which is preferable to successive plantings for the following reasons:

1. The work of planting is all done at the proper time, and one can put his mind at perfect rest on the sweet-corn question.
2. The first and second early are not quite as desirable varieties as the third and fourth varieties; but if the former are not planted, no corn can be picked for the table until the third early "Mammoth" comes, and the ground can all be cleared of stalks, and other crops planted upon the earlier patches.
3. After the Mammoth has been all used whilst just right, the later varieties will just begin to be good, and will continue so until frost.
4. The stalks being of half the value of the crop, are more apt to be cut when green, and in their best condition for fodder; for when one knows there are no more ears to be gathered upon a cer-

tain patch there is no reluctance whatever in making a clean sweep of the stalks at once.

Another important matter we must mention, not generally understood or thought of. Instead of planting long rows, plant each variety as compactly together as possible, that it may fertilize its own ears more perfectly.

The earliest may be planted in hills 3 x 3, or in drills 3 feet by one in the row, the second $3\frac{1}{2} \times 3\frac{1}{2}$, and the Mammoth and later varieties, 4 x 4, or in rows 4 ft. apart and 1 ft. in the rows.

About peas, we would say there has not been as much improvement, with the exception of American Wonder, for first-early; but these, although a very nice pea, are really only a few days earlier than Gems, but no better in quality. There is also a new dwarf, Stratagem, to take the place of Champion as third, which requires no brushing, growing only $2\frac{1}{4}$ ft. How the quality will compare with Champions, this season's experience will determine.

You can not do better than plant all at one time. American Wonder or Little Gems for the first, Advancers for second, Champion or Stratagem for third, and Yorkshire Hero for fourth. When Stratagem are used, no sticks or brush will be required for any, and they will follow each other in regular and happy succession, giving you the very choicest peas in their very prime, from the beginning of the season to its close. All we have said about corn will apply with equal force to planting peas in this manner; even the use of the vines in their green state as fodder is a small item worth saving.

The price of corn and peas is lower this season.

Cleveland, O., April 3, 1885.

A. C. KENDEL.

REPORTS DISCOURAGING.

WHAT IS TO BE DONE IN REGARD TO THE FEARFUL LOSSES OF BEES, ETC.?

I NOTICE in an old number of GLEANINGS your advice is to pay more attention to the department called Blasted Hopes, so as to keep fresh in the minds of the novices the uncertainty of bee-keeping. Well, I suppose this is good advice, but it is wholly unnecessary just now, in this vicinity. We have some of us realized it to be a fact, that bees are sometimes an uncertain quantity. Our empty hives and moldy combs are unanswerable arguments to prove that bees will die sometimes; and a glance around our apiaries demonstrates more forcibly the "uncertainty" of the business than whole volumes of advice. Well, nearly 75% of the bees in a radius of 5 or 6 miles have succumbed to the inevitable this winter. Bee-keeping has been "put back 20 years" by the recent cold winter, so "they" tell us, but we don't believe any such thing. One or two good seasons will repair the losses, and it will "boom" again. By the way, we should like to hear from other neighborhoods and localities, in reference to the losses.

Economy, Ind., March, 24, 1885. G. W. WILLIAMS.

Thank you, friend W., for your kind words. There is one thing we should not overlook in regard to these losses. It is going to open up a trade during the year 1885 in bees and queens, never heretofore known; and our friends in the South will probably have a brisk demand at good prices for every thing in the shape of bees by the pound, in nuclei,

full colonies, and for queens of every shade and color. What is our loss will be their gain. Again, the successful ones who have learned by experience and hard work how to winter their bees safely will this year reap the harvest they deserve. It reminds me of what friend Terry says in the new potato-book. A neighbor of his prepared half of his potato-field just as he knew it ought to be, then he got behind with his work, and short of help, and he fixed the field in the usual way. The result showed that he would have made money to have paid five or even ten dollars a day for sufficient help to have *the work done right*; and this was at a time when plenty of excellent men could have been had for \$1.50 per day. Neighbor H. was in just that predicament last fall. He was building, and neglected his bees, and the loss by this neglect will run up into the hundreds of dollars. We employed a careful hand to care for ours, and he had all the time and help he wanted, and all the granulated sugar he needed, and now we have booming colonies to meet the demand that has come for bees by the pound already.

REPORT FROM INDIANA, ETC.

We put up for winter about 10 colonies in single-walled hives, chaff division-boards on sides, and chaff cushions on top; left on summer stands. Fed $3\frac{1}{2}$ bbls. of sugar late in fall. Considerable remained uncapped. Colonies alive now, 30. That begins to look a little like "progressive bee-keeping." How are yours, friend Root? I have noticed closely for your report, to see how that young man succeeded you told about last fall. The past winter has been the closest I ever knew here. Bees flew but little for nearly 3 months. FRED F. ROE.

Jordan, Ind., March 24, 1885.

See April 1st number, page 248.

ONLY 2 WEAK ONES LEFT OUT OF 65.

I have lost 31 colonies out of 51, and a neighbor of mine saved 2 weak ones out of 65 colonies; and as far as I can hear they have wintered poorly.

A. WORTMAN.

Seafield, White Co., Ind., March 2, 1885.

ONLY 16 LEFT OUT OF 96, AND CHAFF-PACKED.

Bee-keepers in this vicinity are wearing very long faces just now, and, indeed, there is every reason to feel blue. Small bee-keepers have generally lost all. An idea may be arrived at from neighbor Dickenson's report, 16 left out of 96, chaff-packed on summer stands. I can not give an account of my own at present, but know my loss to be heavy.

J. L. COLE.

Carlton Center, Barry Co., Mich., Mar. 27, 1885.

LOSSES IN INDIANA.

I estimate the number of colonies of bees within $2\frac{1}{2}$ miles, fall count, 175; spring, 75. My own, fall, 23; spring, 20. Thanks for the teachings of the A. B. C. Beyond the above limits there are Reynolds Bros., of Williamsburg, our supply-dealers, who have had very little loss; number of colonies kept, about 60. Mr. Replogel, near Hagerstown, one of the most experienced bee-keepers in the county, lost 12 out of about 90; his are in chaff hives. The heaviest losses were where the extractor was used.

A. G. MENDENHALL.

Economy, Ind., March 25, 1885.

RECENT DEVELOPMENTS,

And Suggestions and Queries Particularly Pertaining to the Season.

HEDDON'S HONEY-BOARD.

HOW wide are the slats, and how far apart, in Heddon's sink honey-board? also the thickness and width of the side-pieces and end-bars? Does friend H. use enamel cloth, or its equivalent, above the bees?

North Freedom, Wis.

F. MINNICH.

The slats are one inch wide, friend M. There are 9 of them in all. The outside ones are tight up against the side-strips, and the others are on an average about $\frac{3}{4}$ inch apart; yet in the sample sent us the spaces vary from a little more than $\frac{1}{4}$ inch to a full $\frac{1}{2}$ inch, so I presume the space is not very important. The end and side pieces are $\frac{3}{4}$ thick; the end-pieces are $\frac{1}{4}$ wide in the clear, and the side-pieces $\frac{1}{2}$ inch wide. In making similar honey-boards for the Simplicity hive, we make the slats also one inch wide, and the spaces $\frac{1}{2}$ inch. To make them space the brood-frames and come out right, the two outside slats are only $\frac{1}{4}$ inch. This is because we do not use the sink honey-board for the Simplicity hive, as explained on page 229. I believe friend Heddon does not use enamel cloth at all, or any equivalent to it. The cover to the hive is all the covering he has over the frames or over the sections. I should like to look through his apiary, and see if he or his students do not smash hundreds of bees when they place their cover back on the hive in a hurry.

REVERSIBLE WIDE FRAMES.

Have you ever tried reversible wide frames—that is, wide frames with open top-bars, top-bars same width as the bottom, and the tops and bottoms of section boxes, so that the tiering-up plan could be practised with the wide-frame supers? The frames might or might not be made to reverse. Section cases are growing popular recently, and the chief reason for this seems to be that they can be tiered up, while close-top wide frames can not. If separators are to be used, wide frames are best adapted for this purpose. If nice thick tablets of honey are desired, separators *must* be used. E. E. EWING.

Rowlandville, Md.

Your remarks are good, friend E. The reason why we do not often wish to tier up wide frames is because a complete set holding 58 sections usually give all the room any colony wants at one time. Where we want nice thick cakes of honey, I agree with you that separators must be used. In using wide frames in the house apiary, I thought of setting them in upside down. To do this we should have to have narrow top-bars such as you describe. Projecting ends might be full width. If they were reversed, omit the supporting-arms entirely, and rest the frame on a quarter-inch strip of wood placed on the brood-frames at each end of the hive.

ONE WAY THAT QUEENS ARE LOST.

That queens which fail to return from their bridal trips are generally eaten by birds, or fall into the water, is well known; but that some of them are injured by the entanglement with the drone,

the following would prove: The second year I kept bees I had a large after-swarm; when in the hive two days I watched to see the queen come out (as boys and beginners of all kinds do). I succeeded in seeing her go, when I was called away. In about $\frac{3}{4}$ of an hour, when I came back, the queen had not returned, as the bees were all around the hive, and ready to go some distance to the next colony, which stood on the same floor in a second story over a shop. My brother, who had a mated queen in one of his nucleus colonies, offered the same to me to repair my loss, and we were about to drum the queen out, which was in a small straw hive, as were all our bees at that time. When I went to get something, I passed by the front of the shop, and there I noticed, among the usual number of crippled bees on the ground, a queen hopping around right below the entrance of my queenless hive. She had both wings torn at the ends, and one considerably. I realized the situation, and carried her to the hive at once, when all the bees went in, and happiness was restored. She turned out to be a first-rate queen. We could not but think that the queen had pulled toward home, and separated from the drone in front of her hive, where she fell. I have often thought about the occurrence since, considering all the surrounding circumstances carefully, but could not come to any other than the above conclusion.

Philadelphia, Mar. 9, 1885.

C. H. LUTGENS.

Friend L., I would suggest that your queen got her wings torn by making a mistake, and trying to go into the wrong hive. In such cases the bees will ball and bite them until they present just the appearance you mention. Wasn't that the case?

THE OUTLOOK FOR BEE-KEEPERS.

In view of present prices, has honey and the bee-keeping business any future? How about the survival of the fittest? How about Mr. G. M. Doolittle's estimates; viz., 9 cts. per lb. for extracted and 14 cts. for comb honey? I'd "sorter" like to know, you know. For if any one can produce a good article of extracted honey at low figures, I can! That's one comfort.

CHAS. WATERHOUSE.

Bayou Chene, La., March 23, 1885.

Friend W., you will have to read what Prof. Cook says in his article in our issue of April 1, about the plum-grower, that said the curculio was his best friend, you know. The survival of the fittest is a kind of hard doctrine, but we have to meet it at almost every turn. The parable of the ten virgins strikes right on that point. If our things won't sell, there is one consolation—with the improvements we have, and the recent advances made, we can get a piece of ground and raise enough to live on; and if our products won't sell for money, we will just settle down and be happy without any. I am glad to see you take "comfort," and I guess your ground is good and solid.

A HIVE WITHOUT VENTILATION EITHER UPWARD OR DOWNWARD, AND HOW IT TURNED OUT.

On Nov. 23 I left my home and my bees—70 stocks—four miles distant from the Capitol, to reside in Washington during the winter. I saw no more of my bees until March 6, when I went out home and made an examination of them. I found 10 stocks dead, all late swarms which had not had sufficient honey to winter. In passing on from one hive to another, I noticed one which excited my curiosity.

It was one of your Simplicity hives, which by some accidental oversight in the fall I had placed squarely on the bottom-board, so as to leave absolutely no ventilation. Were they living or suffocated? I first "hefted" it by lifting it bodily, bottom-board and all. Pretty weighty. Then I lifted the hive from the bottom-board, and out the bees rushed *instantly* by hundreds from their confinement of three and a quarter months—the liveliest lot in the whole apiary! This may be a fact of some interest to you in your discussion about "winter ventilation." At any rate, I place it at the service of yourself and your bee-friends. I may add, that the oil-cloth cover was tightly on, on top.

J. K. EDWARDS.

Washington, D. C., March 20, 1885.

Friend E., the above looks a little like a "clinch," but I do not think it is quite, for Simplicity hives as a rule have cracks enough to give about all the ventilation a colony would ordinarily need in winter. But it proves one thing, however, that our fastening bees in their hives is not always detrimental. Accidents of this kind have a great many times demonstrated that bees often do live, in spite of carelessness, and in spite of a kind of treatment (enameled cloth sealed down tight for instance) that our bee-keepers would most of them pronounce "sure death."

THE DISPLAY OF HONEY AT NEW ORLEANS.

I don't think you are doing your subscribers justice by not giving us a report of the honey show at New Orleans. I for one have been waiting patiently for the report. I think it would interest most bee-keepers more than the harangue about the Heddon hive and fixtures that few practical bee-keepers would use. I don't know of what use a bee-journal is if it don't give a report of such fairs as the Orleans show.

LUKE SNOW.

Lamar, Barton Co., Mo., April 1, 1885.

Friend S., although there were a great many fine displays at New Orleans, I do not think among them all was any equal to some we have had at our different fairs. The exhibition at Toronto, for instance, was ahead of any thing I saw at New Orleans. Most of the States made an exhibit of honey as well as other products, and some of them were very fine, but probably not nearly as fine as one singly might have been made had the States all united in getting it up. The exhibits were most of them much like what we have had at our fairs and expositions, and therefore I do not see that it called for any particular comment.

CALIFORNIA HONEY AND EASTERN HONEY.

I have just noticed in GLEANINGS the result of your experiments with the hydrometer on different kinds of honey. You say that the California sage honey is not as thick as the eastern white-clover honey, and that a gallon of the latter will weigh more than a gallon of the former. Now, I think that you are a little "off," somewhere. If I mistake not, you always count your eastern honey at 11 lbs. to the gallon, while our California honey will weigh a little over 12 lbs. to the gallon; that is, a 5-gallon can when full will weigh from 62 to 65 lbs., never less than 60 lbs.

W. W. BLISS.

Duarte, Cal., March 16, 1885.

Friend B., I admit that the California hon-

ey was the thickest, and I expected the hydrometer to rise up higher in it, but it did not do so. The only conclusion I could come to was, that the specimen of clover honey tried alongside of it was remarkably heavy; there were "a good many ounces to the pound," as the saying is. I will make some further tests with the hydrometer, and report.

WHAT TO DO WITH HIVES FULL OF COMBS AND HONEY, WHERE THE BEES HAVE DIED, ETC.

I have been trying to raise bees and make honey several years, but have had bad luck, and get but little honey. Last year and the one before I had over 30 stands and they do not make as much honey as I can eat, and now I have only 16 left. I should like to know how to manage the old hives that have had bees to die in, so when they begin to swarm I can hive them.

JOHN M. ELDRIDGE.

Huntsville, Ala., March 17, 1885.

Friend E., put some more bees into your hives, by all means. You can wait until new swarms come out, and hive them on the empty combs if you choose; but I think a better way would be to divide a strong colony before swarming, and work those empty combs in.

FOUL BROOD WANTED.

I am just in receipt of a letter from Frank Cheshire, of London, Eng., whose investigations in foul brood are well known and valued by the bee fraternity, in which he says: "I shall regard a little piece of comb containing the remains of larvae dead of foul brood as a great acquisition, since it would enable me to determine the identity or otherwise of the bacillus on the two sides of the Atlantic." Will you kindly give this publicity in your valuable journal, so that any brother bee-keeper having foul brood may aid in valuable researches by mailing as requested? His correct address is, Frank Cheshire, Avenue House, Acton, London, England. Any one mailing will be kind enough to pack securely in wadding, inclosed in a wooden box, so that the samples will not be useless when they reach London.

Philadelphia, Mar. 23, 1885.

ARTHUR TODD.

We presume some of our readers will be able to accommodate friend Cheshire. As a rule, however, I object to foul brood being sent around by mail promiscuously; but it may be all right in this case. At one of our conventions, Prof. Cook made the remark that if any professional man wished to make experiments with it he had better go where it was already, instead of having bees shipped to him; but I believe he referred principally to sending an infected colony away for experiment.

DEATH FROM A BEE-STING.

I remember reading in GLEANINGS some time ago what S. A. Dyke said about bee-stings, and I think that his advice to use veils is very good. As a Mr. W. T. Burns, living on West Prairie, Trempealeau Co., while taking the honey from a hive of bees, on the 13th of last August, was stung in one eye, was taken with convulsions, and he died in half an hour. An instance of the kind may not occur again, and then it may—we do not know; and to keep on the safe side is commendable to every one handling bees.

Tomah, Wis., Mar. 20, 1885.

L. S. GRIGGS.

Friend G., this is sad news indeed, and it

may be a good thing for people whose system is very sensitive to stings, to wear veils. I do not believe, however, that I shall wear a veil, unless it is necessary to go out among very angry bees when something usual is going on. I think your caution will have the effect of reminding me not to let a bee get too near my eye. I can pretty nearly always tell when a bee is likely to sting me, and at such times I look out that he does not get a chance. If he is really bent on mischief, I would take time to strike and kill him before going on with my work. I can generally do this by striking him to the ground with my hand, and then putting my foot on him. If you strike a bee down, be sure you keep him down; for if he gets up he will sting you sure. Now, I do not mean because I have said this, that you are to go into an apiary striking and fighting every bee that comes along. Attend to your business, and they will attend to theirs, as a rule. Never stop to strike a bee down as I mentioned, unless it is pretty evident that there is no other way to get along with him. Unless you are an old hand at the business, I do not believe I would advise you to try it, even then.

BEES INTERESTING THE CHILDREN, ETC.

For years I have had such an earnest desire to keep bees, and know something of their wonderful little ways, that my husband, at the last State Fair, purchased me a hive well stocked with bees and honey, from Mr. F. S. Wilder, Barnesville, Ga. Now, if it does not encroach too much on your time, I wish to write you how much pleasure these bees, together with your delightful A B C book, give us. Whenever I open it, every little fellow stands around my knee and listens and laughs as I read aloud to them. Each and all of us have an earnest desire to know you and little Blue Eyes. Do you know any thing of the "dogwood"? Is it a honey or pollen producer? I commenced with one colony, but intend to have a large apiary before I give it up, and wish to know all about bees. My apiary will be exactly like your "Grapevine" apiary.

MRS. R. A. NISBET.

Bloomfield, Georgia.

Dogwood has been spoken of as a honey-plant, but I do not believe it bears very much nectar—at least, the kinds we have around here do not.

WINTERING BEES ON COMBS OF HONEY IN UPPER STORIES, ETC.

I commenced winter with 30 colonies; lost 19. I am not discouraged yet. Last October, when I packed my bees for winter, I left two with the combs in the upper story. They wintered first class. Two-thirds of the bees are lost in this vicinity. I have kept bees for six years, and never lost a swarm by going to the woods. My apiary is within six rods of the woods. I have small trees for them to cluster on. I use the hiving-box, and like it very much; it saves time and trouble. I have the alsike clover, and like it for hay and pasture. I have 8 acres on the ground now.

C. W. POE.

Jones, Mich., March 30, 1885.

CALIFORNIA.

We have had no rain for more than two months, and we are beginning to be solicitous for the future crop. These are usually our rainy months.

Sespe, Cal., March 4, 1885.

R. WILKIN.

TAKING DOWN NOTES.

FRIEND SAVAGE TELLS THE CHILDREN ABOUT WRITING WHAT THEY LEARN.

DEAR BOYS AND GIRLS: We all enjoy reading your letters in GLEANINGS, and seeing the interest you have in bee culture. No doubt many of your communications can not find a place, as there is not nearly room enough for them all. We older boys and girls are sometimes troubled because our scribbings do not appear in print, and we think they are better than yours. But I guess Uncle Amos knows what is best. If you knew him as well as I do you would be sure of that. I'll tell you what we will do. We will have a blank book, and write down all that we do and see done with bees; and by and by, when the big folks are discussing something that they think very important, perhaps we can look over our pages and find something put down, and can give facts and dates that will be instructive, even to those who know a great deal already.

After reading what Mr. Root told the friends at New Orleans about what has been done in bee culture for so many years, I got out some old books in which I used to write down all operations among the bees that I had a hand in, and found many strange things that were not well known at that time, but are now well understood. One book begins 1857, and you will think by that he must be an old boy by this time. Well, he is not bigger than some of you, any way, and often feels "just as young as he used to be." It is very entertaining to read over about those experiments and blunders, and groping in the dark before we had the movable frame and the observatory hive, and many facilities now so common. I think I made some discoveries of things not known, or disbelieved, at that time. I don't think any one had seen a worker-bee laying eggs, and very many denied the possibility of such a thing. Here is an item, Aug. 16, 1864:

"A few drone-cells have been constructed in observatory hive No. 1. In one of these I this day detected a small bee (worker) depositing an egg. On examination, several other cells adjoining and on the opposite side are found to be supplied with eggs, from the same source most likely. I have succeeded in capturing the usurper in the act of depositing an egg—proved to be a worker, being very different from a queen, and by trying to sting when taken. On dissection I found one small egg within. A microscope of sufficient power would no doubt show more numerous proofs of a laying worker."

I did not generally make so long a story unless it was something unusual. To this day I have never seen any account from any one that has seen that process; but now we all know about it, and often to our sorrow. I think there are many things to-day that need your keen eyes to see, and your ready fingers to note down, and you will not have to wait twenty years, and hunt up the fact in an old record book; for now everybody rushes into print, or tries to do it; and if we find out any thing, and can prove it, we may do some good.

By all means have some kind of hive with one comb only, and glass on both sides, so you can see all that is done within—not before it is done, nor after it is done, but while it is doing. But the chief thing that will give value to your observations, both to yourselves and to others, is to write down carefully what you see and do. The great Huber, you know, not only saw but wrote, and his wonderful book was entitled *New Observations on Bees*.

Casky, Ky., March 20, 1885. DANIEL F. SAVAGE.

He that is faithful in that which is least, is faithful also in much.—LUKE 16: 10.

MYSELF AND MY NEIGHBORS.

She hath done what she could. MARK 14: 8.

I OPENED my eyes, and saw daylight just tinging the landscape. Ernest was still sleeping soundly, but we were in New Orleans, and time was precious. Yes, the few hours we had spent there had cost us ~~in~~ cash, perhaps several dollars an hour, and these hours must not be wasted. We were up and dressed while it was yet quite early, and I told him we would go and find a bootblack, and endeavor in other ways to make ourselves presentable before our Southern friends. In front of a barber-shop near by, a pleasant-looking colored boy had established business. His stock in trade was a comfortable easy-chair, with a footstool for his customers while he "made 'em shine." On a peg, at the back of the chair, hung a brush-broom and a good hair clothes-brush. He also had the daily papers for his patrons to read. I did not care to read the papers—I was more anxious to read the boy. He looked thriving and prosperous; and when I complimented him a little, he replied that he had another stand besides this one; and down the street a-piece, across the way, was another colored boy presiding over a similar institution. Before we got through, an old gent came along and proposed to patronize the "branch" shop; but the boy who was hired to take care of it was off looking, or listening to idle gossip. My young friend kept an eye on his apprentice, while he carefully got every bit of the mud out of even the seams of my boots; and when he saw

that he was likely to lose a job by the boy's neglect, he called him to a sense of duty by a peculiar shrill whistle. These two boys, almost of an age, in their conduct plainly showed why one was proprietor and the other simply hired help.

Off at one side was a triangular piece of ground, left by a meeting of two streets, one coming into the other diagonally. This plat had been made into a small park. The park occupied the piece between the two streets, something like the central part of a big letter A. Where the cross-piece is put on the letter A, was a pretty fair-sized two-story brick building, evidently built to give as much room as possible, without much expense. The park contained a fountain, some small tropical trees and flowers, and in the center of it all a piece of statuary in white marble. Whom do you suppose the statuary represented, boys and girls? Some great man, think you? No, it was simply the representation of a pleasant-looking elderly lady sitting in an arm-chair, with her hand laid lovingly on the shoulder of a little girl. I asked my neighbor who was blacking my boots, who the old lady was. By the way, this colored boy was my neighbor, was he not? I do not know why he was not, for he was smart, and diligent in business; in fact, that boy was a model servant to the people. But, more of this further on.

"Why, sir," said he, "that was built after Margaret died. The people of New Orleans raised money and had it made because they loved her. The reason they loved her was because she always loved children so

much. That little girl you see by her side was one of her favorites. She always hunted up the poor children, sir, and finally she was so kind and good to them that the people helped her build that asylum you see." And as he spoke he pointed to the brick building I have mentioned before. Sure enough, there it stood right near the piece of statuary; and across it, in letters dim with time, were words something like these: "Asylum for orphan children."

"I tell you sir," he went on, "you just ought to have seen these streets here at the time the statue was unveiled. There were so many people crowding to get even a sight of it that you could not find a place to stand nor sit down on any of these buildings or in any of the streets. When she died, the people of New Orleans felt awful bad."

I learned from him further, that everybody called her just simply Margaret, and nothing more. I presume, from what he said, that she was not a married woman. Her whole life seemed to have been given to homeless orphan children; and in living for them she was living for the Savior. I gathered from his talk that she was a Christian, and I can readily imagine that when she went home to the Master, her welcome must have been in words something like these:

Come, ye blessed of my Father, inherit the kingdom prepared for you from the foundation of the world: for I was a hungered, and ye gave me meat: I was thirsty, and ye gave me drink: I was a stranger, and ye took me in: naked, and ye clothed me: I was sick, and ye visited me: I was in prison, and ye came unto me.—MATT. 25: 34, 35, 36.

Very likely her reply would have been the following:

Lord, when saw we thee a hungered, and fed thee? or thirsty, and gave thee drink? When saw we thee a stranger, and took thee in? or naked, and clothed thee? Or when saw we thee sick, or in prison, and came unto thee?

For I am sure, from taking a look at that kind motherly face, she never thought, while doing all this little work in building up this asylum for these little ones, that she was doing more than her duty; but I think I may be sure the dear Savior replied to her something like the answer which we see in this fortieth verse.

Verily I say unto you, Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me.

I stepped out of the chair, thinking of this, and rejoicing that I had found traces of the Savior and a Savior's love, right here in the heart of the great city of New Orleans. I told my young friend (yes, by this time he was not only a neighbor but a friend, and I should be glad to see him and grasp his honest hand at any time), that I had got my cloths muddy some, and I wished to get him to brush me up nice, so I should not be ashamed of myself when I rose up to talk to the bee-friends.

"To be sure, sir," he replied, "I always do that." And after he had done his work to my full satisfaction I asked what was to pay. You know, the people of New Orleans have been accused of charging exorbitantly for every thing. Well, I was a little surprised when he said a nickel. He, like Johnny Stout, whom I told you of a while ago, rejoiced in giving humanity "full

value" for all he received. No wonder he had two chairs. Before we took the street-car I glanced again at the beautiful picture in white marble, illumined now by the rising sun, and I thought of Christ's words as he spoke of that other woman, "She hath done what she could."

BLASTED HOPES.

MANY BEES AND FEW HIVES, OR MANY HIVES AND FEW BEES—WHICH?

ONE evening last spring Bro. Phillips came over to ask me if it was not about time for the bees to swarm. I told him that it was time, but that I did not want any more bees, and I was going to run mine without increase, *a la* Heddon, as much as possible.

"Well," said he, "I want mine to swarm; it seems to me that bees do better if they swarm early, and I have a hive down there that is just booming, and I am looking for them to come out every day. Don't you think it would be a good plan to pile straw on the hives and sweat them out?"

"Now, Brother Phillips," said I, "we don't look at bee-keeping from the same standpoint. I run my bees for honey; you run yours for *bees*; you are anxious to have your yard dotted over with little boxes with a few bees in them, while I would have all of mine in one hive if possible, so we must each go our own gate."

In a few days he came up again, and this time he had a smile spread all over his face; his bees had swarmed—swarmed gloriously—three swarms from the same hive, and he rubbed his hands together and chuckled. This was right in the white-clover honey harvest, and my bees were rolling and tumbling over each other to get into the hives with their loads of nectar.

It might have been ten days before I saw Bro. Phillips again, when he said that his bees were doing well; he had nine new swarms, and every thing was humming.

"And how many pounds of honey have you sold?" I asked.

"Oh! not any," he said. "I am not raising honey; I am raising *bees*; and when I get lots enough, I'll put them to raising honey."

Well, he increased his from six to nineteen (I think); then the honey season was over, and it was all the bees could do to live the rest of the time. Last week Sister Phillips was over, and she said their bees were all dead, with plenty of bees and honey in the hives.

This morning as I was driving through town a woman carrying a sleeping baby in her arms stopped me to ask about the bees; hers were all dead but two colonies; had six in the fall; then when I drove up to the grocery, a man hailed me to know how the bees were doing; and he said the bee-keepers along Spoon River that had three and four hundred hives of bees had lost all of them. My friend Ladd, of Ipava, who bought bees of me two years ago, lost all of his, some six or eight colonies (I forget which), and he ought to have lost them, for he never put even so much as a chaff cushion on them, but left them to die. Then when I drove around by the factory, two more men told me of their bee-losses. Friend Hart, of Vermont, Ill., is a scientific bee-keeper. He has his hives in his doorway, and they are painted green and purple and

brown and white, and are very attractive. There they were all winter; but one day we drove by, and not a hive was to be seen. I knew what that sign meant, and although I have not spoken to him about it I know that all his bees are dead.

MAHALA B. CHADDOCK.

Vermont, Ill., March 27, 1885.

A KIND LETTER FROM A YOUNG BEE-KEEPER.

ALSO SOME WISE WORDS IN REGARD TO BEING SICK.

EDITOR GLEANINGS:—I have been studying bee-keeping for three years. During the summer of 1883 I visited the "Home of the Honey-Bees," in company with my father.

We spent a very pleasant day there, and were very kindly treated by the proprietor and his son, who took pains to show us over the factory and grounds. Owing to my occupation, that of railroad station agent, I have not had much time to devote to bees, but have had a few every year since I became interested in them, in order to get practice. Last spring I bought six colonies of a bee-keeper, at \$6.00 each. I let a friend have them on shares, and when they had increased by natural swarming to 18 colonies I sold out, just doubling my money on them.

I have been much helped by the Home Papers. It is my humble opinion, that you are doing a greater work in them than in all the rest; but the bee-work is necessary, in order to gain access to the people, and carry Our Homes to many hungry souls. I loaned GLEANINGS of Jan. 15 to a neighbor. He was so pleased with it he wanted to know if he could get the Home Papers published separately. He did not care any thing about bees, but he liked that number of Our Homes so much he had read it twice. I was especially pleased with the one in GLEANINGS of Feb. 15, under the text, "Fear not, little flock." I fully agree with you, and I am ready to "follow with my coat off."

It seems to me God has surrounded us with innumerable blessings which many do not see, much less take advantage of them. Is there not also another reason than those pointed out by you why so many people, and especially Christian people, fail to get on prosperously? They fail to do their duty in regard to giving of their substance to carry on the Lord's work. Oh if they only knew the blessing that would follow the giving of the tenth of their income to the Lord! Are we not required to give that much? and can we expect to prosper while we wrongfully withhold what belongs to him? He says, "Bring ye all the tithes into the storehouse, that there may be meat, in my house, and prove me now herewith, saith the Lord of hosts, if I will not open you the windows of heaven and pour you out a blessing that there shall not be room enough to receive it."

I should like to give my experience in regard to this matter. A few years ago, both myself and wife had poor health, and were paying out money for doctors' bills and medicine. I was constantly in fear lest I should be thrown out of employment, and poverty seemed to stare me in the face. I had been in the habit of giving more or less at random for gospel purposes, but finally we were led to see that it was our Christian duty to consecrate a tenth of our earnings to the Lord. We began to do so, and this is the result: We were soon led to see that

we should stop paying out money for medicine. God had given us pure air and sunlight, and these, with temperate living, were all the medicine we needed. For over a year we have not used any drugs in our family; our health has become good; we have been prospered in every way. I have saved more in one year's time since we began to give the tenth than in three or four years previously; but better than that, all fear and anxiety regarding our living is gone; we are willing to work; we love to work, and we know our Father will keep his promise. This giving of the tenth is a great incentive to diligence; it is the best cure for discontent and slothfulness that I ever knew of.

HARRY LATHROP.

Browntown, Wis., March 26, 1885.

Why, my young friend, your concluding remarks are a whole sermon in themselves. Saving doctors' bills by lending to the Lord—what a grand thought! And I am just as sure you have got it right, as I am that the air was made for us to breathe.

HAVE AN OBJECT.

Whether therefore ye eat, or drink, or whatsoever ye do, do all to the glory of God.—1. COR. 10:31.

DEAR JUVENILES, do you have an object ahead when you begin to play? Now you know that most people, when they work, have an object; that is, they work to accomplish something. Now, when you commence to play, if you would say to yourself, "I am going to have a good time with my dolly or my dog, now how shall I begin?" don't you think that your play would do you more good, and then you would be learning something besides? May be you can not see what there would be to learn in playing for any especial object. Well, I have seen men, and women too, who would work hard all their lives, and never accomplish much. You see, they had not learned to work to the best advantage for an object, so I want you all to try to work or play so that you can get the most good out of it.

If you do not quite understand me, ask papa or mamma to explain to you what I mean, and don't think, "Oh, I am only playing, and it makes no difference what I do." It does make a difference, if, while playing, you throw things about and leave them so; don't you see you are forming a habit that you may never get over? Now just try to be neat, and teach yourself to put away things you have got through using. You see that you have an object in taking care of them, first, because you will want them again; and second, because a good habit gained is a grand object to attain. Some work or play, as an acquaintance of ours tells a story. He will commence to tell about a certain thing like this: "Mr. Smith was going to harness his horses to go to"—And then he would branch off and tell where he got the horses; what Mr. So and So said, and would go from one thing to another until something would happen so that he would not have time to tell you what Mr. Smith was going to do; and if you were to remind him the next time you saw him of what he had commenced to tell you about Mr. Smith, he would, may be, finish telling what Mr. Smith was going to do, but he would have to tell a great many things first.

Now you see, if you don't look out you may have a good object to work for; but if you don't stick to

that object you will be apt to find that your friends or neighbors will never know what that object is, and your life will be a comparative failure; and no one wants that to happen to them. So, have an object in life, and stick to it.

AUNT KATIE HILTON.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, OF BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books, costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows: viz.: *Sheep, Calf, The Giant, The Kid, The Baby Family, Rescued from Egypt, and Ten Nights in a Bar-Room.* We have also *Our Homes, Part I and Our Homes, Part II.* Besides the above books, you may have a photograph of our old house on any, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

IT is spring time now, dear children; at least, it is quite springlike here in Medina. The grass is beginning to look green in spots, and, oh my! but you ought to see our strawberries. I told you how I fixed the ground last fall, just as Peter Henderson said we should do it. We first made underdrains three feet or more deep, and then we plowed the ground, and subsoil plowed it. Then it was harrowed fine and soft, and then we drew on so much well-rotted stable manure that the men said they could not get it all dragged in; but I told them to drag it in as well as they could, and then we planted right in this good ground, more than half stable manure (that is, it was on top), those nice potted plants I told you about. The plants took right hold of the manure, and grew like cabbages last fall; and when we covered them up in December they seemed to be growing still, and that was the last I saw of them until yesterday, the 6th of April. I went out and moved the straw away from where I supposed it ought to be, and Huber and I both had a jollification over it. Mamma had to come and look too. The leaves were just a bright shining green, and great crowns were already bursting forth with the promise of much fruit. I did not know any thing could be so nice in the way of strawberries. Some of them were covered up with coarse manure, and these look a little the best of any thing. The melted snow and rains, made the past winter, have covered the plants with a dark-colored liquid; but the beautiful green foliage peeping through the manure just makes

me happy. A part of the plants were left uncovered, by way of experiment; but at the present writing, those mulched with manure or straw are away ahead.

I wonder how many of my little friends are interested in strawberries—*strawberry-plants*, I mean. I know you are all interested in the berries; but I tell you, my little friends, if you really want to enjoy berries, you must learn to help raise and pick them. You can not get a real genuine relish in any other way. Now then, if any of you have have any thing to tell about strawberries, I shall be real glad to see it in *your* letters.

GRACIE'S LETTER.

My papa is a doctor. He keeps bees; he gave me a hive, but mine died this winter, it was so cold. He took a trip to Florida this winter, and I guess is enjoying himself.

GRACIE COULTER, age 7.

Marissa, Ill., March 22, 1885.

ALSIKE-CLOVER SEED FOR ONLY \$4.00 PER BUSHEL.

We can not go to school this winter, so we are learning to work and study at home. Lily is two years old. One day mother was mixing bread when she ran up to it and said, "I'll dig, I'll dig," and put her hands into the soft dough. It made us all laugh. Father had 100 bushels of alsike-clover seed last year. He sold it for less than \$4.00 a bushel. We get lots of honey from the alsike. Father has 5 acres of Bokhara clover for the bees next summer.

Whitby, Ont., Mar. 20, 1885. GERTRUDE A. ORVIS.

Well, Gertrude, that is a pretty big fact that you furnish us in your letter, if there isn't any mistake about it. Why should your father offer for sale seed for \$1.00 per bushel, when the market price almost the world over is from \$8.00 to \$10.00? Was it because the seed was not very clean, or because your Canadian market was so completely overstocked? If it had some of your celebrated *thistle* seed in it, very likely the price was high enough.

SEVEN-YEAR-OLD PHEBE TELLS US HOW VERY COLD IT WAS IN CANADA.

I wash dishes, set table, and help mother cook. When we take Lily out of mischief she gets up by us and says, "Watch, watch, watch." It has been very cold here this winter. One night this week the milk froze on the table near the coal fire.

PHEBE ORVIS, age 7. *Per Gertrude.*

Very good, Phoebe; and your sister Gertrude makes a very fair juvenile amanuensis.

ONLY 17 LEFT OUT OF 42.

My father is visiting Florida; he went past New Orleans, and visited the Exposition, and enjoyed it very much. He visited Brooksville last week, and thought it the most beautiful place he had ever seen. He wanted to see if it was a good bee-country. It was so cold this winter, that out of 42 hives of bees he saved only 17. He gave me a hive, and I made \$4.00 from them. He did not make very much from the honey last year. We have an extractor, and I help him extract the honey every summer.

JANIE COULTER, age 13.

Marissa, Ill., March 23, 1885.

And so, Janie, your father is thinking of going to Florida, where bees do not die in winter, is he? Well, you tell him for me not to be in a great hurry about it, for there are some good things about the frost and snows, even if they do kill our bees.

ROBERT'S REPORT.

We have wintered 11 stands of bees. We have lost 3. We are feeding the rest syrup. As cold as it has been, I have been to school every day. I drive the hay-loader and harrow, and drive the roller.

ROBERT McCURDY, age 11.

Hornby, Ont., March 9, 1885.

BAD NEWS IN REGARD TO THE BEES.

Pa says everybody around here is losing most of their bees this winter. Pa has eight in the cellar; they are all right; he left four on their summer stands; two of these died. Does it disturb bees to have much noise in a room over a cellar? Pa says it doesn't. We saw the eclipse of the sun yesterday; it looked like the new moon.

NELLIE A. A. DICKMAN.

Defiance, Ohio, March 17, 1885.

A JUVENILE REPORT FROM CANADA.

This is the village where the Fenians fought our soldiers in 1866. Ma was a little girl then, but she helped nurse the wounded. We keep bees, and pa got lots of honey last year. I heard pa say he doesn't allow any loafing, but he works them for all they are worth. A good many bees died around here, but ours are all alive so far. We pack our cushions with sawdust. I like to help pa with the bees. I shall be 10 years old next June.

Ridgeway, Ont.

SPERRY DUNN.

SEVEN-OLD LITTLE BERTIE'S LETTER.

Uncle Joseph told me if I would write you a letter you would send me a book. I love to read story-books. I have a large kite, and it is real fun to fly it. I have a large ball of cord for my kite.

BERTIE BRIGGS, ages 8.

AND WHAT HIS SISTER MABEL THINKS ABOUT HIM.

My brother is all "kite." He wants papa to get him some red muslin to cover his kite. We have a cow. Her name is Flossy, and we have nice milk to drink. I am six years old. This is my first letter to any one.

MABEL BRIGGS.

Cornwall on the Hudson, N. Y., March 23, 1885.

A COUPLE OF LETTERS FROM THE REED CHILDREN.

My father put in the cellar 32 swarms of bees, and two of them died. My pa is feeding a few swarms. I got stung on the lip once, and it swelled nearly as thick as my foot, and I had hard work to find my mouth. I like bees pretty well, even if they do sting me once in a while. I have been going to school all winter, and I go to Sabbath school too. We have a nice place to make a carp-pond. Pa said he would get some for us as soon as he can.

CLYDE REED, age 12.

My father keeps bees, and he has lost a great many for the last two years. I have a colt, and his name is Prince. We keep some nice Plymouth-Rock chickens. The snow is two feet deep, and it is still snowing.

CHARLIE REED, age 10.

Orono, Mich., March 1, 1885.

HOW PA UNITED A SWARM OF BEES.

HE TOOK THE QUEEN AND ONE WORKER BEE TO THE QUEEN'S HIVE WHEN HE LET THE QUEEN OUT ON TOP OF THE FRAMES. THE QUEEN WENT DOWN ALL RIGHT BUT THE WORKER BEE FLEW BACK HOME. IN ABOUT A HALF AN HOUR THE BEES CAME OUT AND WENT IN THE HIVE WHERE HE PUT THE QUEEN. PA HAS NOVICES EXTRACTOR. I HAVE 4 BROTHERS AND SISTERS. LITTLE BABY BROTHER HAS BLUE EYES. HE CAN TELL WHERE HIS TOE IS AND WHEN HE

GETS ANY THING WITH A HOLE IN IT HE WILL SAY "TEEK" FOR PEEK. HE IS 15 MONTHS OLD. IF WORTH A BOOK PLEASE SEND TEN NIGHTS IN A BAR ROOM.

DWIGHT FRENCH AGE 10

MILLERS CORNERS, N. Y.

ALVA'S LETTER, AND THE REASON HE WROTE IT.

We have four stands of bees, and two of them died. They had plenty of honey to eat, so we took the honey ourselves and ate it. Last year I went to school for eight months, and missed only half a day. I am writing this letter to earn a book.

Harlem, Ia., March 6, 1885. ALVA GOODING, age 9.

Well, Alva, your concluding sentence is very frank and honest. The book was what you were after, was it? The bees died, and you ate the honey. Well, now, I believe I should have got some more bees and put right on to those combs, instead of doing the way you did.

A HILL DEVICE MADE OF GLASS, IN THE LAKE VIEW ORCHARD APIARY.

I am boarding at Mr. Platt's, and he takes GLEANINGS. He keeps bees too, and his bees make the best honey I ever tasted. He has black bees, hybrids, and Italians.

To make an upper passage for the bees to go over from one frame to another, he makes a frame about $\frac{3}{4}$ of an inch high, and lays on it a pane of glass 9 by 12 inches. At the edges of the ends of the glass are small open spaces for ventilation. He says that most bee-men say that is not the right way, but he finds it is a good plan.

Summer before last I spent my vacation in Kansas, and I found gum-weeds on the prairie. The flower looks something like a small sunflower.

Mr. Platt's apiary is called the Lake View Orchard Apiary.

CHESTER EDMONDS, age 12.

White Plains, N. Y., March 23, 1885.

WINTERING BEES OVER THE KITCHEN.

I am a little boy ten years old. My pa has six stands of bees; he put them up over the kitchen this winter; sometimes they come down in the kitchen, and bother us; do you think that it is a very good place to keep them? My grandpa had 167 stands last fall, but they are pretty nearly all dead. I am at my grandpa's now. I like to stay out in the country.

ELDON S. R. HAYES.

Wilmington, Ohio, March 31, 1885.

Why, Willie, it does not seem to me that it would be a very good place to winter the bees; but if your papa got them out all right, while your grandpa, who did not put them over the kitchen, had them die so badly, the evidence seems to be rather in your favor. I do not think I should want to winter bees anywhere where they would be getting out of their hives in winter.

PAPA'S HOUSEKEEPER.

I take pleasure in writing to you. I have a little sister; her name is Matta. Our mother is dead—been dead ten years. I am papa's housekeeper. I help papa with the bees. I can sew on the machine, I can make shirts and pants, and my dresses, and I can cook. We have had some very cold weather. Pa is planting Irish potatoes to-day, and bedded sweet potatoes also. I raise a great many chickens. We live close to the railroad; the cars, pass on one side of us, the boats on the other side. We live on a nice little farm on Red River. Pa

has got a great many bees; this is a good country for them.

PERLINA MORGAN, age 12.

Boyce, La., Feb. 14, 1885.

Dear me, Perlina! so you are planting potatoes away down there, are you? Do you know, that since reading the proof-sheets of our new potato-book I am just getting wild to plant potatoes?

NAOMI'S DESCRIPTION OF A JUVENILE WINDOW GARDEN.

Grandma takes GLEANINGS, and we like it very much. We have 19 swarms of bees. One day last summer, when papa was away, we had a swarm to hive, and my eldest brother and I took our first lesson. Our bees did well last year. I have three brothers, two older and one younger than myself. They all go to school, and I am taught at home. Mamma has been blind seven years. Grandma and I read GLEANINGS to her, and she enjoys the juvenile letters and Our Homes. I like much to hear about Huber. I think he would like our new way of window gardening. Fill a glass with water, and tie a thin cloth over it, then scatter turnip seed on the cloth, keep the glass full of water, so that the seed will be moist, and you will have a cute little garden.

NAOMI D. RHODES, age 9.

Locust Grove, Va., March 18, 1885.

Thank you, Naomi; and Huber and I are going right to work to make just such a window garden, and when the turnips get up we will report. Pretty good for a nine-year-old little girl.

LENA'S ACCOUNT OF THE WAY HER FATHER PREPARES HIS BEES FOR WINTER.

I live on a farm. My father keeps bees; he has 13 Langstroth hives; he has kept bees since 1867. He sold one year 1200 lbs. of strained honey. He has got a "slinger." He said he was going to get a new one in the summer. Father takes GLEANINGS. I like to read the stories very much. He has a little building he calls his office, where he slings out honey. I will tell you how father keeps bees in the winter. He takes the honey-board off, and in its place he puts a kind of arched rack over the lower story, or breeding apartment; on this rack he covers with woolen carpeting in squares, to cover the bees up warm. He uses 4 or 5 thicknesses; he has tried several other ways, but likes this best of all. He wintered them this way six years. He has used the racks 4 years.

LENA WILCOX, age 12.

Onleyville, R. I., March 27, 1885.

Very good, Lena. So your extracting-house is the "office," is it? I presume that, with such a dignified title as that, the room will always be kept nice and clean. If that is the case, I think such a name is a pretty good thing. I will explain to our readers, that with the above letter Lena sends a very good drawing of her father's wintering-rack. It is a sort of Hill device on a large scale.

WILLIAM'S ACCOUNT OF THE REVIVAL.

While I was at school to-day our folks opened the hives and there was brood in every hive, and young bees in all the hives. They cover the combs of three frames in each hive, and in the hybrid hive that had one drone in October, the drone is still there. We fed them to-day for the first time, with rye flour and thin syrup. They saw the queen that is in the hive belonging to my brother and me.

There has been a glorious revival in this town.

At the Methodist church, 87 joined, all of whom were converted, and about 3 more converted besides. Last Sunday the Friends' church commenced a series of meetings, which have resulted so far in six conversions, and last night three arose for prayers.

WM. M. NORDYKE.

New Vienna, Ohio, March 21, 1885.

Friend William, we have had a glorious revival in our Methodist church too; and the best part of it is, that a number of boys and girls belonging to our factory are among the new converts.—I am glad to know your bees are doing so well.

ALBERT'S REPORT.

My pa and one of our neighbors sent off for a foundation-machine to Mr. Given in April, but we did not get it till the middle of October; but we heard that it was in the Toronto custom-house. The expenses and all together cost us \$73. We have had some very cold weather here during the winter. Last year was not a very good one for bees here. We extracted over 300 lbs. of honey last year.

ALBERT McCURDY, age 13.

Hormby, Ont., March 9, 1885.

But, friend Albert, you did not tell us whether the delay was caused by the manufacturers or by the custom-house officials—perhaps a little of both. It seems to me our friends in Canada, with all their other good qualities, should have enough good feeling for the wants of their fellow-men to notify them when things were lying at the custom-house. We have had some pretty severe trials with the slowness of the makers of the Given press, as well as the Canada custom-houses.

RACHEL'S REPORT; MORE TESTIMONY IN FAVOR OF SUGAR SYRUP.

I have had several circulars addressed to me from bee-keepers, they thinking, as you headed my letter in your journal, "Ray and his Chickens," I was a boy too. We have had a very cold winter; bees that are chaff-packed out of doors have got badly hurt. Pa had nine colonies and five nuclei out of doors, and they are half dead. Pa says there are about twelve in cellar that have dysentery; he says that they are old colonies, and that it is caused by the honey-dew, as those that had white-clover honey and sugar syrup are in very good condition.

RACHEL ADDENBROOKE, age 11.

North Prairie, Wis., March 16, 1885.

We really beg pardon, Rachel; but we would advise you in future to either give your whole name, or make it clear in some way that Ray, in your case at least, is a girl's name. Sometimes mistakes of this kind are a little embarrassing, and we want to avoid them.—I think you are right about it, that it was the honey-dew that killed the bees. Neighbor H. has lost very heavily from this trouble. Last fall, when he was fixing his bees for winter, he found one very weak colony that was clear out of stores, and starving to death. He felt so sorry about it that he gave them two big milk-pans of sugar syrup as fast as they would take it, so as to be sure they would not get that way again. Well, this 2d day of April they are one of the best colonies he has, while great strong ones with natural stores died.

OUR HOMES.

And God called the dry land Earth; and the gathering together of the waters called he Seas; and God saw that it was good.—GEN. 1: 10.

ALl my life I have been deeply interested in any thing pertaining to old Mother Earth; and just as soon as I was old enough I began questioning as to what there was away down in the ground. I looked into the deepest wells I could find, but saw nothing very satisfactory down in their dark depths. Wherever I saw a bank that had caved off, or whenever the road had made a deep cut through a hill. I was deeply interested in seeing what the hill was made of. Once my father pointed to me a large rock partly covered with ground, while we were riding along through the country. How I did use to enjoy those rides with my father! Very likely it was just about as Huber now enjoys walks and rides with me. Dear old father! how it thrills my heart when I think that he loved me (yes, loves me now; am I not right?) in just the way Huber and I love each other. Well, when he told me that this rock, of which we just caught glimpses, was, perhaps, miles and miles long, and miles and miles deep, my little heart was stirred to know more of these great rocks. When excavating and tunneling for railroads, where a passage has to be made through these great masses, it is a great treat to study their structure and their inner composition.

When I got old enough to study geography, one of the first things that took my attention was Mammoth Cave. I was told that there was a place in the world where we could go away down into old Mother Earth, and then I read of the strange things that were told about this wonderful cave, with its little lakes and rivers, and fishes without eyes. In later life I many times thought of that old Mammoth Cave, and sighed to think that may be this life should be passed, and I should never even see that fond dream realized. After deciding to go to New Orleans, however, Mr. Holmes said one day we could stop off at Mammoth Cave if we chose. Now, I did not tell anybody, but it was the truth, that I looked forward with more pleasure to this one feature of my trip, than perhaps all else besides. Mr. Holmes gave me a little circular published by the railroad company, and I studied this a good deal on the way. When we took the sleeper at Cincinnati, a couple of young men got on who told the conductor they wanted to be called in the night, to get off at Mammoth Cave. When I knew we were in the region of the cave I could hardly sleep; and as soon as I caught a glimpse of the gray dawn of morning, my nose was pressed against the window-pane, trying to get a glimpse of the wonderful country that furnishes such a phenomenon of nature. Before I knew it I was abundantly rewarded. I had calculated that, in this cave region, the water, instead of running along the top of the ground, as it does in Ohio, would probably meet fissures in the rocky landscape, and go down into the caverns. Well, I saw a little

rivulet running down the hillside, from the melting snows of spring. Not a great distance from the railroad track it ran into a sort of valley, and gurgled down into a hole, and that was the last of it. I wondered if my eyes had played me a trick in the dim light of morning. But pretty soon another and then another, and finally a pretty good-sized river just came right out of the side of the bank, and traveled on its course, as if that were the way rivers usually do. We were in the cave region, truly. By the time Ernest awoke, these strange sights had disappeared; but on our return trip we came through by daylight, and watched eagerly for them. These "sink-holes," as they call them in Kentucky, are quite frequent, I am told, and in some places they annoy farmers exceedingly, because of the good ground that washes down into the hole, and leaves them nothing but the bare rocks. In a few cases I saw where they had thrown in rails and bushes in trying to stop the water. What a grand opportunity our friends down in Kentucky have for underdraining! But, perhaps, like ourselves, they do not half realize the blessings that surround them.

When we approached Cave City I was almost breathless with excitement. Ernest and I sprang from the train, hurried up to a hotel where a big sign-board announced, in dilapidated letters, that stages ran twice a day to the cave. We were somewhat taken aback, however, when the clerk told us they could not send a team right away, unless they could have seven passengers, and the charge would be \$3.00 each. Before we reached Cave Hotel, however, nine miles away, we thought the trip was worth \$21.00, for much of the time the hubs of the hack-wheels rode on the mud, and it took us three hours and a half to make the nine miles. In answer to my question, the driver admitted that they had, during the past winter, paid out enough money for horses to have almost, if not quite, built a plank road over this space of nine miles. But they are not Yankees, and do not have Yankee grit. Weary, cold, and hungry, we finally pulled through the mud up to the landing at Mammoth-Cave Hotel. The young lady who officiated as clerk said we could not have supper for about an hour and a half; but when I asked her if there was not something we could go and see, to keep us busy and out of mischief, she said that we might go down and look in the mouth of the cave, if we chose; and then, if we were not too tired, we could go and see Green River, and this river communicates with the rivers of the cave, you know. Ernest and I scampered off through the garden like a couple of schoolboys. We went to a gate at the back end, and followed a path down the hill among the rocks. The rocks in the region of Mammoth Cave are not like the rocks here. Instead of being sharp and angular, the most of them look like a piece of ice that has been left standing on the sidewalk a great part of a summer day; that is, the corners of the stones are rounded off, and worn in channels and gutters by the storms and rains. I judge from this that the rock is composed of some material that is soluble in water, and the water had wash-

ed it away. Flutings and carvings, produced by the agency of the water, are sometimes curious and beautiful. The streams, also, have a color to them, sometimes red, sometimes yellow, owing to the rocky matter they hold in solution. This is what gives both color and name to Green River.

Well, after we had followed the well-worn path down quite a piece, we came to what we judged must be the mouth of the cave. It is a great sort of cavern, or opening, in a gorge in a hill-side. A little stream pours down directly over the mouth of the cave, and forms a tiny waterfall; but when the water strikes the bottom it does not run anywhere, but just goes into the rocks out of sight. Nearly one hundred steps, fashioned in the rocks, took us down to the floor of this cavern, and we walked along a sort of shelf, or ledge, until we got out into the darkness. Ernest was ahead, but called back to me that there was an iron door across the opening, and that we could not go any further. Just then I kicked a loose stone, and it went rattling down into a chasm, and I called to him to come out, and be very careful, or we should get into some fearful abyss, to pay for not waiting for the guide and lights.

As we came out of the mouth of the cave we noticed a tombstone. On reading the inscription we found it was the grave of Stephen Bishop, almost the first original guide, and one of the most daring explorers of Mammoth Cave. He spent his life among its strange labyrinths; and when he died he was buried near his old home. Although we had many miles to walk in the cave that night, I told Ernest that I wanted to see Green River; and so, down, down, down, we went, until it seemed as if our pathway would never reach the valley. It did, though, and the sight of the river amply repaid us. A way off through the trees I caught sight of another smaller river coming out of the side of the mountain. I told Ernest I could not think of going home until I had seen that. This river came out of a sort of cave, as it were; and were one in a boat he might sail into the mountain quite a little distance.

When we got back to the hotel we were ready to enjoy an excellent supper, you may be sure. We found the other five of our company sitting by the fire, some of them smoking. How *can* people sit down by the fire, and loaf away time when it is so precious? Here we were at Mammoth Cave, and the expense of getting here had been such that every hour we remained would represent several dollars in cash. It seemed to me almost too bad to take time to eat supper; but after supper I was tempted to feel discouraged when we were told that the party would not be ready to visit the cave before nine or ten o'clock. The bright, intelligent clerk, though, evidently understood her business, and she entertained us during these hours with descriptions of the cave, telling us what route would be the one we had better take, and giving us some of the legends of the place.

I want to digress a little here to point a moral. All through life we meet not only with vexed but disappointed people. Most of

of us, too, meet with opportunities of softening vexation and disappointment, to say nothing of opportunities of banishing it entirely. Most of us are serving our fellow-men in some capacity or other. The traveling public are constantly looking to others for what they need; and it is not only *servants* and *clerks* at hotels, who have it in their power to make people comfortable and happy, but it is almost every one of us. Jesus said, "He that will be greatest among you, let him be your servant." Unfortunately, however, none of us like to be servants; and yet that is just what we are; and the way to be happy is to enjoy being a servant. Sometimes you say, "I am not going to be anybody's servant." Suppose, now, dear friend, you should say, "I am going to be everybody's servant." How would that sound? Well, the proprietors of the hotel at Mammoth Cave had the good luck to secure a clerk, or book-keeper, who seemed to feel that the place whereunto God had called her was in being everybody's servant. She was not called upon to bring wood for the fire, or to put out the horses, it is true; but she "served" by making people feel pleasant, and willing to wait. I thought once her gift was a rare one; but in thinking it over I do not know that it is so very rare after all. There are thousands of young ladies (I know two over at our house) who can make themselves very pleasant and agreeable if they have a mind to try. Perhaps you have seen girls in their teens take pain to make themselves agreeable to certain young men. Did they succeed? May be some of you can remember how well they succeeded. Ask your wife if she remembers any thing about it. Well, now, suppose these same girls should exert themselves just as much to entertain some old lady, or, may be, a fidgetty, notional old man, or perhaps half a dozen boisterous men of the world—business men, for instance—would they succeed? To be sure, they would, if they tried to. I do not know whether this young lady of whom I am speaking was a Christian or not; but I do feel that she honored her Savior in being agreeable and entertaining for three or four hours, to a party of seven who were impatient to visit the cave. Some of this party smoked cigars meanwhile, right in her presence too; but she looked cheerful and happy for all that.

I inquired eagerly how it was that so many people could be found who could go on foot the eight or nine miles we expected to go that night, and not become fatigued. She said the air of the cave seemed to have a wonderfully exhilarating effect on almost every one, and that many people would go the entire long route of 18 miles and not mind it. She herself had traversed it, and felt well enough to attend a ball in the evening afterward. I shall have more to say of this anon.

Daniel Boone was one of the first who assisted in exploring Mammoth Cave. In 1812 quite a business was done in mining saltpeter to supply our people with the materials for making gunpowder during the war of the above date. One of the first explorers was a man named Baker. He wandered in

a short distance by the help of a torch, and told his family, when he got home, of such wonderful sights he saw, that his wife and three children accompanied him back. They became so interested with the rocky formations that they wandered on until he stumbled and dropped his torch. He tried to light it again, but failed, and for two days and two nights they wandered in its awful darkness. Finally his wife sought for the spots made by their damp feet when they came in, and by this means got near enough the entrance so they could see light.

In 1816 the cave was owned by Thomas Moore, but he was ruined by being connected with the Burr and Blemmerhasset conspiracy. At one time a Mr. McLane bought the cave for \$40.00, and 200 acres were thrown in to make him satisfied with his bargain. In 1837 a Mr. C. F. Harvey was lost in the cave for 39 hours. His fright became so great that he lost his mind; and when the guides got track of him he fled from them like a wild animal. He recovered, however, after being among his friends for a time.

One of the romantic features of the cave is, that for more than sixty years people have hunted for some other opening, and many attempts have been made to sink a shaft that should strike some of its subterranean caverns. Stephen Bishop, whose tombstone I have mentioned at the mouth of the cave, once discovered a second opening. He was a slave at the time; but his master, who owned the cave, hearing that he knew of another outlet, questioned him about it. He admitted that he did know of such an entrance. In order to prove it beyond doubt, his master, with old Matt Bransford, the one who was to guide us during our trip, went and placed themselves at the mouth of the cave, sending Stephen in, and locking the iron door, they both keeping watch at the entrance. If he got out without coming through that door, of course they had proof of the other opening. Along in the afternoon he came quietly down the side of the mountain. Now, the other opening might be on some other man's land, and the cave was getting to be valuable property. Said his master,—

"Stephen, if you will give me your promise to carefully close this secret opening you have discovered, so that no one will ever be likely to find it, either on the outside or inside, and then will agree to let the secret of it die with you, I will give you freedom."

Stephen gave the promise; and although he lived many years afterward, the secret was kept locked in his own breast, and he died with it. Our narrator informed us, with a sly twinkle, that he never told even his wife!

There are in the Mammoth Cave, 223 avenues already explored, and the united length of these avenues is equal to 150 miles. The short route takes in eight or nine miles of the most interesting portion; and the long route, which crosses the rivers, and includes a boat-ride on one of them, is about 18 miles. At the time we were there, the rivers were too high to permit of taking the long route.

Pretty soon a horseback messenger informed us that the other party for whom we

were waiting were not a great way off. Old Matt, our guide, trimmed his lamps and prepared for the trip. He was quite talkative, although he was an old man, and seemed quite willing to be plied with questions. The lamps were about the size of a tin cup, set in the center of what looked like a tin plate, and three chains enabled us to carry them conveniently. The tin-plate arrangement was to prevent breaking the lamps by knocking them against the rocks. Each visitor has a lamp and a cane. The time for starting arrived; but, as usual, two or three of the company of eleven were lagging behind. My friend Matt finally pulled a rope and rang a bell that was perched on a post near us. Even then they would not all come without considerable urging. I felt like dancing around the guide, like a schoolboy who is going chestnutting; but I concluded it were better to remember that I was almost an old man, the father of a family, and—editor of GLEANINGS; so I walked soberly, but I was not behind anybody, you may be sure. Here we go, down the gravelly walk, and we are actually before the mouth of old Mammoth Cave. The little waterfall makes a pleasant ringing as it spatters among the rocks. Our party of eleven are in good spirits, and down we go those rocky steps till we stand before the mouth of this great cavern—one of the wonders of the world.

I wanted to run on ahead, but our friend Matt objected. The iron gate across the narrowed-up passageway before us made me think of the wicket-gate in the Pilgrim's Progress. Matt was our interpreter, and I hope we were all Christians. We stood around him while he unlocked the gate and swung it back on its hinges. Just now we began to discover that our guide was to be *boss* during the evening, and we were to be his subjects. He ordered us to hold our lamps before us, and walk straight ahead until he called on us to halt. Somebody ventured to ask what we were to do that for, and he simply replied, "Do as I tell you."

We found out pretty soon, for the breeze that was coming out near the entrance now increased to almost a gale, and it was with difficulty that we kept our lamps from blowing out. This iron gate is about 300 feet from the mouth of the cave. When the guide called on us to halt, we looked around and discovered that the ceiling had raised, and the walls had receded until we were in a large room as it were. All around the sides of the room were bats hanging to the walls and ceiling. Now, Ernest once had bats for a hobby; and for a week or two he questioned everybody he came across, as to whether they knew any thing of these animals that could fly, and yet did not have feathers. His grandpa gave him the most information of anybody, but still he was not half satisfied. I turned to him and told him now was his time to push his investigations. The guide told us they came there to wait for summer.

"Why, Matt," said I, "you do not mean to say these chaps hang here in this way from fall until spring, do you?"

"That is exactly what they do do," said he.

"But, what do they have to eat?"

"They do not eat any thing."

Now, here is a point for friend Clarke in his hibernating theory. The droppings from the bats had accumulated in such quantities that they formed a sort of guano, which had been collected for fertilizing purposes. Some of the boys proposed catching some of them to take home; but the guide told them there would be plenty of time when we came back, and they need not fear but there would be plenty of bats, for, in fact, there were thousands upon thousands. They came in just far enough to be entirely beyond the influence of cold air—perhaps 500 or 600 feet from the mouth. The temperature of the cave now became uniform, and stood at just 55, and it seldom varies one degree from this, winter or summer. Here is a fact for us in wintering bees. Old Mother Earth is 55, and I presume the water from our deep wells is 55, or ought to be. Isn't that where we want it? and if so, can we not get it without any very great trouble?

A little further on we came to the vats and machinery used by the saltpeter makers over 70 years ago; and yet every thing was as perfect as it was the day it was put up. Woodwork never decays or wears out here. We somewhat expected to find dampness; but the floor is covered with dry dust in many places, and in this dry dust you will see footprints made by the barefooted boys of a century ago, it may be. The guide told us to hang up our overcoats on the timbers. Some thought they would rather carry them; but he told us we should not need them, and that we had better follow his instructions. I had been troubled with a cold and sore throat, so that I thought I might be chilly; but I very soon discovered that there was no danger of taking cold in Mammoth Cave. We now began to discover the queer figures on the ceilings and walls, formed by the precipitation of plaster of Paris, or sulphate of lime, formed by the water years ago, when these caverns were water-courses. These salts, as they were precipitated from the water, crystallized in many curious shapes, sometimes resembling frostwork on the window-pane, or alum crystals on the alum baskets that we used to make when children. A great part of Mammoth Cave was originally strewn with pieces of broken rock. These have been piled out of the way, so as to make it convenient for people to pass. Matt rapped with his cane on a log along our pathway, and explained briefly, "Pump-logs of 1812." Our forefathers carried water into the cave by these pump-logs from the little waterfall over the mouth, that I have mentioned. After passing it through the saltpeter dirt, just as we pass the water through a barrel of ashes in soap-making, they carried the saltpeter in solution back to the mouth in another set of pump-logs, making, altogether, more than half a mile of these wooden pipes. When the water came back it was boiled down in kettles as we make sugar.

After our overcoats were off, and we were ready to start on our tramp, the guide gave us some directions in regard to getting lost. Visitors are requested to keep their eye on

the guide, and note carefully his instructions. If one should, however, become so intent on examining some of the curiosities, and forget and let the crowd get out of sight, all he has to do is to keep right where he got lost until his absence is discovered and they come back after him. If he will do this, he will be certain to be rescued inside of ten hours, because the whole route the guide traversed will be gone over in that time, under any circumstances. If, however, he thinks he can manage it himself, and goes to wandering about in the avenues and darkness, it may be impossible to find him for several days. During the route the guide would call out, "Danger on the right!" and again, "Danger on the left!" Whenever these calls came I was always curious (like old mother Eve) to know what it was that was dangerous, and what made it dangerous. Sometimes, by peering off toward the danger I could discover a steep precipice, with rough and ragged rocks away down at the bottom. Sometimes these chasms were fenced off with a railing. Where there was an abundance of room, safety was secured by simply walking far enough away from the brink. The caution was needed, however; for a careless person, amid our talking and laughing and jesting, might stumble, without thinking, into these dangers; for these little lamps that we carried seemed to have little effect in dispelling that darkness for only a few yards ahead.

Did it ever strike you, dear reader, that we all, in living these lives of ours, need a guide to warn us beforehand of danger on the right and danger on the left? Do you remember what I have told you of that little voice within me that calls out, "Lord, help," sometimes before I am scarcely aware that dangerous ground is near? I have thought, too, of the way in which we sometimes try to get ourselves out of trouble without any help from the Guide. A young Christian makes a mistake innocently. He feels ashamed to confess his folly, and, without waiting for the Guide to tell him what to do, he ventures to try a falsehood as a refuge. He gets in trouble and darkness. Instead of standing still and falling on his knees, asking mercy and guidance, he tries more falsehoods, and soon finds that he is blundering hopelessly in a darkness that is even worse than the darkness of Mammoth Cave, and more dangerous and more sure to lead to ruin than any foolish blundering in that cave. In Mammoth Cave they have what they call the Bottomless Pit; and one who blunders alone, without the assistance of an experienced guide, might possibly fall into it; but he who disdains and rejects the help of the Savior shall surely reach, in the end, that *bottomless pit* that many of us have, even yet in these lives, had faint glimpses of. Shall we not, then, dear friends, keep closely to Him who has said,—

I am the light of the world; he that followeth me shall not walk in darkness, but shall have the light of life?

And now, friends, here I am at the end of the fourth page of my story, and yet it is scarcely begun; and therefore I shall have to continue it in our issue for May 15.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,

EDITOR AND PUBLISHER.

MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, APR. 15, 1885.

God resteth the proud, and he saveth grace to the humble. - 1. PETER 5:5.

BUSINESS AT THE PRESENT DATE.

As we are still up with orders, discounts will be the same as on page 248, last issue.

OUR NEW POTATO-BOOK.

WE hope to have this ready to be mailed in about ten days. It seems to me the book must certainly be worth the small price asked for it, to every one who is even *indirectly* interested in the cultivation of the soil. We make this proposal: We will send it by mail postpaid for 40 cts.; and after you have read it through, and you do not say it is worth the money, you may send it back at our expense, and get your 40 cents.

THE CANADIAN BEE-JOURNAL.

THE initial number is at hand, and it certainly gives great promise of much usefulness. Its motto is, "The greatest possible good to the greatest possible number." If friend Jones can keep a weekly bee-journal going, and make each number equal to the one before us, it will, without question, have a wide circulation, even throughout the U. S., and may be some of the brethren may decide to take the *C. B. J.* instead of *GLEANINGS*. Dear me! what a calamity that would be! But if it carries out the spirit of friend Jones's little text, I think I can say amen, and not be troubled either.

HONOR TO WHOM HONOR IS DUE.

MR. JOHN DARR, of Darrrtown, Ohio, sent us a letter Feb. 10, describing a wire reversing device, nearer to our own than any thing else that has appeared; in fact, it was just about it exactly, only he had just one arm for the frame to hang on. I at once decided that it was impracticable, because frames balanced on a single pivot were used and discarded years ago. What I did was to make two arms and a larger hole in the end-bar, so that there were two supports to the device. I should have mentioned this before, but I had forgotten that such a letter had been received till he called my attention to it. He also mailed me a sample device.

MAKING FIGWORT AND SPIDER PLANTS GROW.

ALMOST every spring we have more or less complaints about these seeds, and, to tell the truth, they are a little bit shy about vegetating. We have just discovered, however, that they all come up beautifully, and in a very short space of time, when managed on the plan Peter Henderson gives in his *Garden and Farm Topics*; namely, covering the seeds with sifted moss instead of earth, and then keeping the moss damp by sprinkling on water every day. As soon as the third leaf is well out, the plants should be transplanted an inch or two apart.

Our friend "Lu," the botanist of our office, by request also furnishes me the following:

Take a common flower-pot with a hole in the bottom, and fill with earth as for potting a plant. Sow the seeds in this carefully, cover with earth, and pack down well all around, and water well. Turn over this a glass goblet that will fit tightly in the top of the pot. Fill a saucer with water, set the pot, goblet and all, in it, and place the whole on the reservoir of the kitchen stove. Ours is an old fashioned elevated reservoir. Always keep the saucer full of water, and no matter how hot the stove is, it will be all right. By this method, spiderplant seed will sprout in four days. As soon as you see the earth "humped up" in little heaps you will know that the seeds have started, and should remove the pot to the window and give all the sun possible.

WHAT IS TO BE DONE WHEN THE BEES ARE ALL DEAD?

WHY, put some more bees in the hives, to be sure. At this season of the year, half a pound of bees with a queen put on to combs of honey will make a good colony by July 1, with proper attention. There is a little trouble, however, in getting so small a quantity as half a pound to take care of the eggs the queen will lay, unless the weather is favorable. A little piece of brood to hold the whole together, even though it were no larger than a cookie, would keep the little colony together; and the young bees that would come out of such a piece of brood would come in just the right time to keep the thing going. Now, I do not believe very much in sending off to supply-dealers for half-pounds of bees with hybrid queens to get a start, so long as you can buy bees for any decent kind of a price around home. You may have to send off for queens, because old-style bee-keepers would not have as many queens as you need. But bees and brood can almost always be bought near home. In order to cut the little piece of brood I spoke about, take just such a cookie-cutter as you have to cut out cookies. Take a comb out of your old hive. Cut out a circle. Then with the same cookie-cutter cut a circle out of the brood-comb. Swap the pieces, and you have no mutilated combs to bother. If the cake-cutter does not cut the combs readily, file it sharp, and then roll it around as you make the cut. If your time is limited, it may pay you to buy several packages containing half-pounds of bees, and a cheap queen of some kind. Some years, after bees have died, we have done quite a trade in sending out hybrid queens with half-pounds of bees each; and the friends who bought them, I believe, did nicely with them too. They will cost more during the month of May, but they are worth almost as much again as if bought a month later. If the weather is nice you can get along without any brood; but a little piece, such as I have mentioned, just about such as the bees can cover nicely, will be a great help. I suppose every thing in the shape of a queen, black or hybrid, will be eagerly bought up this season; and it would be a great boon to the friends who have lost, if those further south would put up half-pounds of bees with a cheap queen, at a moderate price. A thousand such packages would be a real blessing now, and I will give the names of reliable men one insertion, free of charge, in our May number, who are prepared to ship promptly, at a low price, just such packages. While there are thousands who have lost all their bees during the past winter, and have nothing but empty hives and empty combs, there are still other thousands who have wintered splendidly, and who would doubtless be glad to divide with the sufferers, at a moderate price. Now, friends, let us help each other. As I am situated I do not well see how I can sell for less than advertised prices; but I hope there are hundreds who will undersell me. What we do sell in the way of queens and bees we expect to have go promptly, and we want to send queens as we have heretofore, the very day the order is received, the season through.

A HINGED ALIGHTING-BOARD.

G. F. HILTON, Fremont, Mich., sends us a sample chaff hive having a good-sized alighting-board

hinged just below the entrance. The hinges keep the alighting-board securely in place, and let it drop down at any convenient angle, while if the hive is ever to be shipped it turns up over the front, so it will not get knocked off, and it is entirely out of the way.

SECOND-HAND CIGAR-BOX PLANER FOR SALE.

We have one of the above planers that has been in use in our factory for two or three years. The price of such a one new is \$70.00. This one is all in good order, with an extra pair of new knives that have never been used. As we have taken it away to give place to a larger one, we will sell it for an even \$45.00.

FRAME-REVERSING DEVICES.

At the present writing, five different individuals claim our reversing device as their own invention. Now, these five different devices are not at all alike; in fact, one would hardly recognize them as being alike in any respect, and mine is certainly like none of them. It seems to me there is a bad spirit getting in right here, and I do not know but a bad spirit is getting into me too. Even the Howes reversing device proves to be over ten years old, as you will see from friend Flory's description in another column. No doubt I have used features in my device, belonging to each one of the five; but, where shall we end, if we go on in this way? that is, each one of us claims to be the original inventor of every thing that uses *even a small portion* of something embodied in our invention.

SENDING US SAMPLES OF BEE-HIVES.

If any of the friends wish us to look at the hives they have made, of course we can not very well object; but I hope when they do, they will pay the express or freight on them clear to Medina. I hope, too, they will not feel hurt if after we have looked it over we send it right back again. Our attic is not big enough to store away bee-hives; and after the experience we have had storing them away in our warehouses because there is a *possibility* that they may be needed some time, we think it much the better way to send them back to the shipper. We are often requested to set them in our apiary, and give them a trial. And now, dear friends, please do not think me uncharitable when I say that, when we have attempted to do something of this kind, it has always proved a *trial*, but in another sense of the word. It is not unlikely there are better hives in use than those in our apiary; but the expense of making changes is so great that we feel as if we would rather take the chances with what we have.

MORE COMPLICATIONS.

In our price list we have for some years advertised a honey-board. A few months ago friend Hutchinson invented a queen-excluding honey-board made of wood. We had honey-boards made of perforated metal before. Right away after, Mr. Heddon said Hutchinson's honey-board was "no good," and so he gave us a real genuine honey-board for an eight-frame hive. That makes four kinds of honey-boards. Well, just as soon as they were illustrated, somebody wanted the same thing made for the Simplicity hive. Others will probably want them made for the American hive, for the Gallup hive, etc. There are four different kinds of honey-boards, and they are wanted for four different kinds of hives. That makes a stock of sixteen kinds of honey-boards that we must have on hand to accom-

modate the brethren. Now, friends, this is entirely out of the question. We will try to keep in stock, for prompt shipment, the four kinds of honey-boards to fit the Simplicity hives or chaff hives (which is the same thing), but I am afraid we shall have to be excused from making these same to fit other kinds of hives. The above gives you a little glimpse of the sea of confusion we shall have in bee culture, if we do not come down to uniform dimensions, and stay there.

A WOMAN'S SEED-CATALOGUE.

We have received a four-page catalogue from Mrs. Jennie Frances Belden, West Branch, Michigan, and Mrs. B. certainly offers seeds reasonably enough. Flower-seeds are 2 cts. per paper; very choice varieties, 4 cts. per paper, and novelties come up to the extravagant sum of 5 cts.; garden-seeds, 4 cts. per packet, and our friend assures us that the varieties she offers are carefully selected from the best known. She says, "My garden is my pride, and I grow no poor plants in it." She pays all postage, but no order is accepted for less than 10 cents. For orders running from three to five dollars, a still further discount is offered. Now, the point that strikes me is this: Why can't a woman do this work? Women, as a general thing, would be more honest than men. Perhaps they could afford to work cheaper because they have no tobacco nor whisky bills to pay, and I really believe that many a woman could make a very nice little business in the way our friend has started out. Of course, the quality of the seeds sent out would determine whether the business would build up or not. She says her seeds were all raised in 1884, and were all tested in December. It has occurred to me many times while working in the greenhouse lately, that a great part of this work is emphatically woman's work. All that is wanted is a woman that loves plants and flowers, and a woman that is willing to work, and wants to make her way. The price list mentioned is nicely arranged, but the printing is very poor. If Mrs. Belden would like to reward us for the good notice we have given her business, I wish she would let us print the next catalogues she needs.

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

Such a brisk demand has sprung up for this, and our customers seem to be so much pleased with the goods, we have succeeded in getting another still larger lot, of one of the largest manufacturers of wire cloth in the world. Please bear in mind that the only way in which we can afford to sell it at the very low price of 1 1/2 cts. per sq. ft. is by selling the entire piece just as it is put up. We have now in stock the following pieces. As fast as it is sold, each piece is crossed out, and the next issue will show what remains.

SOME OF THE USES TO WHICH THIS WIRE CLOTH CAN BE APPLIED:
This wire cloth is first quality in every respect, and is just the thing for covering doors and windows, to keep out flies, for covering bee-hives and cages for shipping bees; making sieves for sifting seeds, etc.

"THE CONQUEROR."

BORODINO, N. Y., Aug. 15, 1882.—All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am boss. Bingham's Conqueror Smoker did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE.

BINGHAM & HETHERINGTON
UNCAPPING KNIFE.

PATENTED, MAY 29, 1885.

The Original
BINGHAM
Bee Smoker

Patented, 1878.

Prof. Cook, in his valuable Manual of the Apiculture, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that no one but Bingham has been able to

improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of blocks and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, much or little, swift or slow, just as you please, any or all of the time; top up or down, they always go!

Bee-keepers will save money and vexation by buying genuine Bingham smokers and Bingham & Hetherington Uncapping-Knives first. We neither make nor handle any other supplies; but of these we are the original inventors, and only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint. With European and American orders already received for over 3000, there is evidence that 1885 with us is not likely to be an idle one. Also that such goods as we make have met the advanced wants of the most advanced bee-keepers in Europe and America.

Prices, by mail, postpaid.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for advertising them up and keep them in stock, and yet it is oftentimes quite an accommodation to those who can not afford higher priced ones.

QUEENS FOR SALE.—Hybrid queens, 50 cts. each; black queens, 25c. each, from June 1 to Oct. 1. Safe arrival guaranteed. R. H. BAILEY.
7-11db P. O. Box 81, Ainslie Forks, Essex Co., N. Y.

I will sell 20 hybrid queens during May and June at 40c each; will ship them as I can spare them; safe arrival guaranteed.

W. A. SANDERS, Oak Bower, Hart Co., Ga.

I am killing black queens daily. Have 20 of the best ones left. If you want one or more for 25 cts., order quick.

J. P. CONNELL, Hillsboro, Hill Co., Texas.

I have some cheap queens; 3 hybrids at 60c each, and 12 tested Italian queens at \$1.25, the 1st of May. I will also sell some bees, five frames with tested queen, at \$4.50 per colony.

W. A. COMPTON, Lynnville, Giles Co., Tenn.

I have for sale 15 hybrid queens; will sell the best ones at 50c each; second grade at 35c each.

LOUIS WERNER, Edwardsville, Madison Co., Ill.

I can furnish 25 fair to good hybrid queens at 50c each. WM. ST. MARTZ, Martinsville, Ill.

As I will Italianize about 80 colonies during May, June, July, and August, I will sell black queens at 25 cts. Will begin to ship May 20. Also six hybrid queens at 50 cts. each, ready to ship now.

E. W. STAYTON, Martin, Weakly Co., Tenn.

PURE ITALIAN BEES

Full Colonies, Nuclei, and Queens a specialty. If you intend buying bees or queens this season, send for my circular and price list. You will save money by so doing. 7-11db

C. C. VAUGHN, Columbia, Tenn.

SECOND-HAND FOUNDATION MILLS.

We have at present two mills which we have taken toward new ones. The first one is a 9-inch Washburn mill; price, when new, \$30.00 or \$40.00. We will sell the mill for \$12.00. The second one is a 12½-inch mill, such as we used to make for the L. frame. We will sell this for \$18.00. It has a stand so it can be set directly on the floor.

All the above-mentioned mills have been worked over so as to make the new style of cell. Samples of the work will be sent on application. We will allow 5 per cent off from prices mentioned above, for cash with order. A. I. ROOT, MEDINA, OHIO.

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or \$2.00 per year.

\$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or \$2.00 per year.

Those whose names appear below agree to furnish Italian queens for \$1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for \$1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

BEE-KEEPERS!

Headquarters for all kinds of Bee-keepers' supplies, such as Hives, Sections, Comb Foundation, Honey Extractors, Bee Smokers, Crates, Honey Buckets, Veils, etc., etc.

Notice Our Prices!

7 lbs. All-in-one-piece Section, \$4.50 per M.
 Comb Foundation, \$5.00 per lb.
 Hives, \$1.00 each.
 Italian Bees and Queens at low figures.
 Send name and address, and we will mail you our latest *Illustrated Catalogue* from
American M'tg Co., New Carlisle, O.

PLYMOUTH ROCKS.

Exclusively bred on a farm, and for business, of the best of strains, regardless of cost of breeding, by 5 years' experience. Not excelled in penciling, scoring, and shipping. Eggs warranted of best vitality in hatching. Satisfaction guaranteed. Price, with packing and shipping, \$2.00 per lb., or \$3.00 for 25. The cost of packing and shipping may be deducted for those who can get them without. Chickens in season. Apply for prices.

9d **J. D. ADAMS, Nira, Wash. Co., Iowa.**

Reduction in the price of Comb Foundation.

Owing to the large quantity of wax thrown on the market by the recent losses, and the general depression in business, we have decided to quote comb foundation, on and after May 1, at the following prices net:

1 to 25 pounds, per pound	47c
25 to 50 " " "	46c
50 to 100 " " "	45c
100 to 500 " " "	44c
500 to 1000 " " "	43c
1000 pounds or more " " "	40c

Packed in neat wooden boxes paper between every two sheets.

If wanted by mail, add 25c per lb. for boxing and postage, on any quantity less than 2 lb.; over 2 lb., add 25c for boxing and postage. 12 x 18 can not be sent safely by mail, in less quantities than a 3-lb. package, and we can not put up less than 1 lb. any size. Now, all of you that will order in our regular-sized sheets, 8 x 10, or 12 by 18, or 8 x 12, may have it for 1c per lb. less. If you will also order it in our regular-sized boxes of 5, 10, or 25 lb., you may deduct 1c more lb. Thus, 1 lb. by mail, regular size will be 20c; 3 lb., \$1.45.

83 (weight or express)	
7 lbs. regular sizes will be	\$1 75
5 " " " " " " "	2 25
10 " " " " " " "	4 50
25 " " " " " " "	11 00

VERY THIN drone or worker 7th, for comb honey, 10c per lb. extra. This we intend to run at least 10 square feet to the pound, and it will be made in strips from 3 to 5 inches wide.

HONEY COLUMN.

CITY MARKETS.

CINCINNATI.—*Honey.*—Nothing new has transpired in the market. Demand has improved for good qualities of extracted honey, but the large stock on the market keeps prices low. It brings 50¢ on arrival. Comb honey is of slow sale, and a low price is no inducement to the buyer. Prices nominal. *Beeswax* is in good demand, and arrivals are good. It brings 20¢ to 30¢ on arrival. Chicago takes the cake on adulterations. We had lately several lots of adulterated beeswax offered us from Chicago merchants, which was hard to tell from the genuine.

CHAS. F. MUTH.

S. E. Cor. Freeman and Central Avenues.
April 23, 1885. Cincinnati, Ohio.

NEW YORK.—*Honey.*—These is no notable change in the honey market since our last. The demand for both comb and extracted is very limited, only small lots being disposed of at low figures. We make no change in our quotations. *Beeswax* is holding its price. We quote prime yellow Southern at 33¢ to 34¢ per lb. THURBER, WHYTELAND & CO.
April 13, 1885. Reade and Hudson Sts., New York.

ST. LOUIS.—*Honey.*—Our honey market continues very dull. Extracted in bbls. hard to sell. Last sales at 4¢ for Southern. Stock large. Comb honey. White clover, single case, 1-lb. sections, 16¢, in good order. Cases having broken combs, less. Dark comb not salable. *Beeswax* in fair demand at 28¢ to 31¢; not much arriving, stock small.

W. T. ANDERSON & CO.

104 N. Third St., St. Louis, Mo.

CLEVELAND.—*Honey.*—There is a little better trade in honey; we sold some first-class 1-lb. sections the past week at 13½¢ to 14¢; there is no better sale for second quality, which we hold at 12¢ to 13¢. Extracted, no sale at all. *Beeswax*, 28¢ to 30¢.

April 20, 1885. A. C. KENDEL.

115 Ontario St., Cleveland, O.

KANSAS CITY.—*Honey.*—There are a good many scattering lots of honey coming in from sources which were thought to be exhausted of their supplies long ago; and while the demand continues to improve, yet prices rule entirely in buyers' favor. Choice stock 1-lb. sections, 13¢ to 14¢; 2-lb., 12¢ to 13¢. Extracted, 50¢ to 75¢.

CLEMONS, CLOON & CO.

April 27, 1885. Kansas City, Mo.

MILWAUKEE.—*Honey.*—Clover and basswood honey in comb, quotable at 12¢ to 13¢. Dark, 10¢ to 11¢. Strained and extracted, 1½¢ to 8¢. *Beeswax*, 30¢ to 35¢. Demand light, and trade dull.

April 20, 1885. A. V. BISHOP.

142 West Water St., Milwaukee, Wis.

DETROIT.—*Honey.*—Stock of honey on hand rather low, and demand only fair. Price 12¢ to 14¢.

April 21, 1885. A. B. WEED, Detroit, Mich.

BOSTON.—*Honey.*—There is no change in our market. Honey sells slow now on account of maple sugar and syrup. BLAKE & RIPLEY.
April 13, 1885. 57 Chatham St., Boston, Mass.

FOR SALE.—Four barrels of honey-dew in new iron-bound barrels and half-barrels, for which I will take 4 cts. per lb. JOHN F. DIPMAN, Fremont, O.

I WANT TO SELL OUT.

I HAVE for sale about 40 Simplicity hives, 1½ story non-movable bottoms, painted with two coats of white lead one year ago. They have metal rabbets and metal-cornered frames (upper corners only). Frames are full of good combs, and probably more than half full of honey; 30 racks (mostly home-made) for holding 28 sections; 90 wide frames full of boxes and starters, with tin separators. How much am I offered for the lot on cars—cash?

GEO. H. PATCH, STEVENS POINT, WIS.

FOUNDATION.—Who wants it for 40 cts. per lb.? 200 lbs. in the lot, ready made, and will be cut to fit any frame. T. S. Hall, Kirby's Creek, Ala. 9-101

Where Can I Get 40 or 50 Nuclei of Italians the Cheapest?
EASTGATE HUMPHREY, Rodney, Elgin Co., Ont., Can.

HELP FOR THE SUFFERERS.

The following friends have agreed to furnish bees and queens at low prices, for the benefit of the friends who have lost badly during the past severe winter. In consideration of this, they are allowed to give the following notices once free of charge. As will be noticed, the prices are more or less lower than our regular advertised rates.

BEES BY THE POUND.

200 Colonies to draw from. Safe arrival guaranteed. Send for circular before purchasing elsewhere.

T. P. ANDREWS,

Farina, Fayette Co., Illinois.

In June and July, at \$1.00 per lb., 10 lbs., 90¢ per lb.; 20 lbs. or more, 80¢ per lb. Queens to go with them, \$1.00 Nuclei, as per A. G. ad. Orders filled in the order received. J. H. REED.

ORLEANS, ORANGE CO., IND.

We are now ready to supply bees by the pound; also a limited number of queens. We have never had a case of foul brood or any other bee disease in this region; and for "get up and dust," early and late; and 100 lbs. of honey to the colony, we say our strain of bees can't be beat. Those wanting bees from us can correspond.

J. C. & D. H. TWEEDEY, SMITHFIELD, OHIO.

During the months of May and June I will sell Black Bees by the lb. at 75¢. ½-lb. 50¢. Black Queens with same 25¢. as long as they last, or will mail Black Queens for 35¢. Safe arrival and satisfaction guaranteed. MRS. J. ATCHLEY, LAMPASAS, TEX.

I will sell dollar Queens with a pound of bees with each queen for \$1.50. JOS BYRNE, BATON ROUGE, LA.

After May 15, I will supply ½-pound lots of bees for \$1.00. JOHN H. MARTIN, HARTFORD, N. Y.

We will sell as follows: ½ pound bees, \$1.00. Untested queens, \$1.00. Tested, \$2.00. The above queens are reared from imported mothers, and the bees will all be young Italians.

DIXON & DILLON, PARRISH, ILLS.

We are prepared to ship promptly by Am. Ex. Co., ½ lb. hybrid bees with good hybrid queen in wire cage, at \$1.50; 1 lb., and queen, \$2.00; ½ lb. black bees with good black queen, at \$1.25. Hybrid queens, 50 cts. Black queens, 25 cts. Sent by mail in a Peet introducing cage. Safe arrival guaranteed. None to sell after May.

HEMPHILL & GOODMAN, ELSEBERRY, LINCOLN CO., MO.

We will furnish ½ lb. bees and untested Italian queen, for \$9 in ½ doz. lots, or \$1.50 each, by express Wells, Fargo & Co. from New Iberia, La. J. W. E. SHAW & CO., LOREAUVILLE, IBERIA PARISH, LA.

After June 1st, hybrid swarms at \$2.00. May have some as early as May 15th.

E. BURREE, VINCENNES, KNOX CO., IND.

I have 200 nucleus colonies of hybrid bees on L. frames. We will sell at \$2.25 each, on 2-frame; \$3.00 for 3-frame. Ready to ship at once. Strong in bees. First come, first served. Bees are at express office now. T. S. HALL, Baldwin, Miss.

½ lb. bees and queen, black, \$1.00; 1 lb. do., \$1.25; ½ lb. bees and queen, hybrid, \$1.25; 1 lb. do., \$1.50. Queens only, mailed at 30 and 60 c. Stamps accepted, and safe arrival guaranteed. J. M. JENKINS.

Elmore, Elmore Co., Ala.

I can spare a few pounds of bees, and as many queens as any of the brethren may want. I will sell bees at \$1.00 a pound, and queens at \$1.00.

S. G. WOOD, BIRMINGHAM, ALABAMA.

Vol. XIII.

MAY 1, 1885.

No. 9.

TERMS: \$1.00 PER ANNUM, IN ADVANCE.

TO TRAP CURCULIO.

PROF. COOK GIVES US A LITTLE TALK ON PLUM
CULTURE.

PROF. A. J. COOK: While reading your excel-
lent article on "The Wintering Problem in
Apiculture," in this month's GLEANINGS, I
thought that, as many bee-keepers are inter-
ested in fruit culture, in asking you to favor
the readers of GLEANINGS with an article on plum
culture, having particular reference to Judge
Romsdel's method of dealing with the curculio, I
would express the wish of many others. Should
you find it convenient to contribute such an article,
there will be one at least who will be greatly obli-
ged to you, and I think many others. If you do not
care to do this, and it is not asking too much, I
should like to have you tell me by letter how to
manage the "little Turk," and I will consider it a
great favor. Respectfully yours, RUFUS PORTER.

Lewistown, Ills., April 15, 1885.

Replying to the above, Prof. Cook says:

Quack methods are often given in our papers. A
few years since, I read in a paper that winding a
cloth about the trees, and saturating it with crude
carbolic acid, would surely keep the "little Turks"
at bay. I tried it; but fortunately on only one tree.
As I visited the tree during the sultry June days,
the whole atmosphere was odorless with the acid,
yet I could see the little weevils thick on the plums
of this tree, plying their mischief, and, as I fancied,
fairly grinning their "you couldn't come it" at me.
But I did succeed in one thing. I killed a valu-
able plum-tree outright. I already knew of a valu-
able and thoroughly effective method, yet was
not content to let well enough alone.

THE JARRING METHOD.

This is the method used by Judge Romsdel, and
has saved the plums in my own little orchard year
after year, so that we and our neighbors had abun-
dant. A sheet of common factory cloth is nailed
to a light convenient frame, and large enough so
that, when spread under the tree, it will catch every
thing that may fall from the tree. I have only four
trees. My sheet is twelve feet square. Along one
edge this sheet is tacked to a strip of light pine,
twelve feet long. The opposite edge is tacked to
two similar strips, each six feet long, the break be-
ing in the middle. From this break the sheet is
slitted to the center. This slit makes it easy to
place the sheet directly under the tree, the center
of the sheet inclosing the trunk of the tree.

In case of large orchards it is found better to
have this sheet carried on wheels, or attached to a
sling, so as to be easily borne on the shoulders. In
place of the wheels or a sling I have two little
children, which, by the way, no family should be
without, by aid of whom the sheet is quickly and
easily manipulated. Besides the sheet, we must
have a strong heavy long-handled mallet. This
may be thickly padded with carpeting—this is the
way mine is fixed—or a limb may be sawed off, or a
spike may be driven into the trunk and main
branches to receive the blow, in which cases the
padding of the mallet should be omitted. What we
desire to do is to give the trunk a sharp blow so
that each limb may be jarred with force, and yet
not injure the tree. Small trees may be jarred by
simply striking the trunks. With large trees each
branch must be jarred.

The time to commence the warfare is just as we
see the little eggy crows falling from the plums.

or when we see the little crescent cuts thus, (•), on the plums. These little curved cuts are made by the little weevils as they lay the eggs in the plums. This fact gives rise to the name "little Turk." For years now I have seen these crescent marks just as the blossoms—calices—were falling from the plums. The jarring should be done very early in the morning, or as late in the evening as we can see well. To avoid the dew, not to speak of early rising, the evening battle is generally preferred at our house. In the middle of the day, especially before the days get warm, the curculio are hid beneath the trees, hence the necessity of jarring as early or late as daylight will permit.

We spread the sheet under the tree and then strike the trunk, or, in case the tree is large, each main branch. A sharp blow is required, as only a sudden jar will surely fell all the weevils to the sheet. The spike or padded mallet permits this without injury to the tree.

As soon as the jarring has been thoroughly done, we examine for the insects on the sheet. These little beetles look so like the little bugs that will be dislodged by the same blow, that only sharp looking, especially at first, will detect them. Each year I perform this before my thirty or forty students, and often they will declare the first night that there is not an insect, when perhaps there are a score on the sheet. At first, pick up every thing that looks like a little bug, and learn by close scrutiny whether it be bug or insect. If the latter, it will soon move when taken in the warm hand; we soon get so we see the weevils very quickly. Bertie and Katie are a great aid to me in, catching the weevils, as well as in moving the sheet. It is great fun for them, as they eclipse their father in the number caught. To kill the insects we crush them between the thumb and finger. This is quick, sure, and not disagreeable, as the insects are so small. Often we may omit the jarring for two or three nights. If we get no curculio, or only two or three at a tree, we can safely wait a day or two before we try again. It is often safe to omit jarring for two or three days. I have found that I have to work more or less all through June. This is for central Michigan; and taking the years together, I have not had to jar more than fifteen times in a season. This seems little labor when we consider the results—plenty of luscious plums to sell and to keep, or, best of all, to give away to our good neighbors.

It is a good idea, though I have never done it, to gather all the plums that fall, and burn them. This prevents the development of the insect—now a grub, feeding on the pulp of the plum—and so makes the insect more scarce the next season.

The reason Judge Romsdell, Michigan's great plum-grower, thinks the curculio an advantage, is that it can be kept under, and the plum crop saved. Most people, through ignorance or neglect, will not do this, and so plums will always be scarce, and always bring a high price in the market. Again, when the trees set very full, the plums should be thinned; by allowing the curculio to sting a portion of the fruit, the thinning costs nothing.

A. J. COOK.

Agricultural College, Lansing, Michigan.

Last fall, just about plum time, I visited one of our bee-men, friend J. Mattoon, of Atwater, Portage Co., and among other things I took a look at his plum-yard. This yard was not very large, but it was filled with the

most luxuriant, thrifty-looking plum-trees I ever saw before in my life; and if I remember correctly, he said he had just sold fifty bushels of plums out of that "chicken-yard," and that he received for them an even \$200. The trees were got into bearing shape by underdraining, subsoiling, use of fertilizers, and all modern improvements. Then chickens enough were kept in the yard to keep the ground as hard and bare of vegetation as it usually is for a few rods around the front of a country schoolhouse. The trees were jarred in the way Prof. Cook mentions, but the chickens gobbled the curculios, rendering the use of a sheet unnecessary. Friend Mattoon succeeds with bees, plums, pears, strawberries, and every thing of the kind. Do you know why?

After the above article was in type, we received the following letter from Prof. Cook, touching on another subject:

POLLEN AND WINTERING, AGAIN.

We have just had a bad mishap with our bees; but it gives forth clear evidence on the pollen question. Our bees were in fine condition March 1st. Our cellar has six inches of water in it, and keeps a uniform temperature from 38° F. to 45° F. By an accident, mice got into the cellar, and so worried the bees in three hives that they ate all their stores, what the mice did not eat, and starved. Of the remaining colonies, six had much pollen. Four of these have diarrhoea very badly, the other two considerably, but not seriously. The colonies having no pollen have no diarrhoea, and are in fair condition, though their combs and hives are badly knawed by the mice.

I think I can say truly, then, that bees are safer in an atmosphere that is too cold or too warm, without pollen, and also decidedly safer in case of an invasion of mice. March 1st there was no sign of diarrhoea. Whatever disturbs bees will endanger them in case pollen is present, and confinement necessary. Keep the bees quiet, and the pollen is harmless—so I think, as the result of several winters' close observation and experiment.

April 25, 1885.

A. J. COOK.

APIS DORSATA.

FRIEND BUNKER TELLS US ABOUT HOW THESE BEES BEHAVE IN THEIR HOME IN BURMAH.

DEAR BROTHER ROOT:—I have just returned from the hills, and while traveling I have been studying *Apis dorsata*, and now make a report of progress. There seems to be two kinds of this bee in Burmah, each quite distinct, though I have not yet secured specimens for comparison. One kind is yellowish in color, and usually builds nests on the limbs of very high trees, or in rocky cliffs, while the other is nearly black, hairy, and builds in thickets, on limbs of trees, or on creepers, often near the ground. Both are unicombed bees. The former is often vicious, the latter kind is very gentle, according to all reports, and the natives have no fear of it at all. They often approach the nest of the latter by daylight, and take off pieces of comb, without smoking or protection of any kind whatever, and without often being attacked by the bees. The former kind defends its nest with great vigor; and if they once set

upon an enemy, they follow very persistently for a long distance, and sometimes natives thus pursued must take to a neighboring stream to escape.

One ruse for escape is to break off a thickly leaved bush and plunge into the water, and allow the branch to float down with the current, while the fugitive plunges down into the water. The bees then follow the branch down stream, and lose sight of their victim. Yet, the first kind with the yellow markings is not always so vicious, as they can be easily subdued with smoke; and if handled carefully they seem to be as gentle as many kinds of *Apis mellifica*, so I judge. Both kinds leave Burmah at the beginning of the rains, and return the first of February of each year. They usually return to their former place of abode. This is especially true of the yellow kind, which occupies a chosen tree or trees in a particular locality year after year, so that the natives buy and sell these trees as valuable property.

I judge that these bees migrate to some distance to the north, for these reasons: 1. The reason why they migrate at all, seems to be the exposed position of their nests, on the under side of the limbs of high trees, exposed to all weather. The high winds and violent showers of the beginning of the monsoons would always destroy their nests. I never saw a nest survive the rains; hence, migrating on account of the rains, they must needs go to a climate where the rains are less violent, or where they can find sheltering cliffs in which to build. 2. When they return they are often found resting near the ground, before selecting the tree on which to build a new home. Sometimes they will rest there a week, and then take flight again. At such times they are very cross, and the natives are very careful not to go near them. There are no cliffs or rocks in Burmah in which these bees can build. If there were they might remain here the year round, as I understand they do in Ceylon and in Northern India.

In the Padung-Karen country, about 80 miles N. E. from Toungoo, these bees are in some sense domesticated, also the *Apis Indica*. In order to secure the service of the *A. dorsata*, the Padungs dig a trench in a side hill, and drive a stout stake, inclined about 45 degrees toward the down slope of the hill, into the ground, and lean branches of trees against the stake on either side, making a shield from the wind. The *A. dorsata* returns to these places year after year, and the natives secure bountiful harvests of wax and honey, always leaving some for their yellow workers. May it not be that the *A. dorsata* builds one comb, only because it does not usually find a place to build double combs? The comb is so large that it must indeed be a large limb of a tree to give room for double combs. From all inquiries which I have made, I am strongly inclined to believe that the *A. dorsata* can be domesticated, especially the black-colored species. Yet, to insure success, doubtless much study must be given to the habits of this bee, and all the conditions of domestication be approached as near as possible to their wild state. The fact, as I am informed, that, in regions of less rain, in cliffs and rocks these bees are found year after year, goes to show that migration is not necessary to this bee as to "birds of passage," etc.; that if the conditions are favorable they may be kept the year round. The fact that these bees can be mistaken for hornets by the natives, as in Mr. Benton's experi-

ence in Ceylon, shows how little we can depend on their judgment in such matters.

I now have two swarms of the *A. dorsata* promised me, and men out after them. Of course, I am now speaking of this bee only from report, and very little from experience. I hope in due time to speak from experience, and have something of value to report on this most interesting insect.

Toungoo, Burmah, Feb. 28, 1885. A. BUNKER.

[For later report, see page 314.]

MRS. JENNIE CULP'S REPORT FOR 1884.

AND A FAIR REPORT, EVEN THROUGH THE BAD SEASON OF LAST YEAR.

I AM again so late in sending my report, I fear, Bro. Root, you will say of me as the good sisters at camp-meeting say, "Sister Culp always brings up the rear;" and I will add, especially if it is her day to do the cooking. I received a postal from one of your clerks some time ago, saying, "We want your report, if it is a failure." Now, what possessed her to think I had failed? Was it because she saw me up at Medina visiting when I ought to have been home looking after my bees? or was it because she knew we had extremely hot dry weather in our part of the State? Be that as it may, I am not ready to go into the failure list yet. No, no; for surely Providence smiled upon me again, but not in such a bountiful manner as the preceding year.

Fall of 1883 I put into chaff hives 47 colonies; all came out in good condition; and as my object was honey, and not increase, I prevented swarming. The indications were that the honey season would be of short duration. I extracted but once, taking 1740 lbs. of beautiful white-clover honey, and 350 lbs. of section honey; in addition to this I set away 100 frames of nice white-clover honey averaging 10 lbs. per frame, for winter feeding; also had 100 new wired frames filled with fldn. drawn out ready for this summer's work. In the fall, removed the "bug-juice," gave them the white-clover honey, and, as a consequence, to-day, Apr. 16, 1885, 46 out of the 47 were out on duty strong. A great many in this locality have lost three-fourths of their bees; some all. We are not so badly off as the good brother at Bowling Green represents his county to be; we still have enough left for "seed."

MRS. JENNIE CULP.

Hilliard, O., Apr. 16, 1885.

Thanks for your report, my good friend Mrs. Culp. I presume the reason why that postal read as it did, was probably because I happened to think of you, and so told one of the girls to ask you for a report, adding that we wanted you to send it, *even if it was a failure*. They probably got hold of the last end of my remark, and omitted the first part. I have thought a good many times that probably some of the friends would think we are a queer sort of people here; but with the hurry and rush of many duties, it was the best I could do, and so it went. I am very glad indeed to know you have wintered so well; and your report strengthens still more my opinion, that those who take pains will prosper.

The hand of the diligent shall bear rule; but the slothful shall be under tribute.—Prov. 12:24.

HOW FAST DOES A SWARM OF BEES TRAVEL?

FRIEND BRAYMAN SUGGESTS THAT THEY SOMETIMES GO FAST, AND SOMETIMES THEY GO SLOW.

NOW, Bro. Root I call you brother, because I believe that all good Christians are brethren, for our Master said, while here, that "He that doeth the will of my Father which is in heaven, the same is my mother, my brother, and my sister"), I want to say a little about how fast bees fly when going off, for I had a little experience with some last season. I had a very large swarm come out on a Thursday, and I hived them and placed them where I wanted them to stand, and they went to work all right, as I supposed, for they commenced to draw out the comb (from fdn.) and filled each frame nearly full of nice white comb, and stored some honey. On the next Monday forenoon, about 11 o'clock, another swarm came out, and I hived them all right; but having occasion to go and help a neighbor raise a barn-frame in the afternoon, I left No. 2 swarm where I hived them, till night, before moving them to where I wanted them to remain. While I was gone that afternoon, swarm No. 1, which I hived Thursday, came out of their hive, and clustered upon an apple-tree, and my wife took another hive and hived them in that. When I came home at night I placed them both, Nos. 1 and 2, upon stands where I wanted them to remain. On Tuesday I went out and looked at them, and No. 1 was restless and uneasy. I told my wife that they would not stay, or, at least, I thought they would not; so I went out about every 15 minutes to see how and what they were doing.

About 12 o'clock I went out, and they appeared about the same as usual. I went in and had not sat down more than five minutes when my little boy came and said, "Papa, your bees are swarming."

I went out, and I saw that they were not going to cluster, for they rose higher than usual, and were making quicker motions than a swarm that clusters. Soon I saw that they were making across my orchard. I started after them. Well, how far do you suppose I went before I lost all sight and hearing of them? About 15 rods. I gave up the chase, and turned around and came back, and lo! No. 2 had caught the spirit, and they were tumbling topsy-turvy over one another, as if they could not get out fast enough. I lay by the hive waiting for the queen, and the good wife watching where they were going to cluster; but, nary a cluster; they, too, started for the woods, but in an opposite direction (east) from the others. I followed them; some of the time I walked, and some of the time a little faster, till I came to the tree into which they went. Now, I believe it makes some, if not all of the difference how far they are going, how fast they fly.

Waldo, Wis., Apr. 15, 1885.

A. H. BRAYMAN.

You make a good point, friend B.; and, by the way, is it not true that it is difficult to lay down rules for a great many of these things? Sometimes bees behave one way, and then again they don't. I have seen a

swarm of bees moving overhead when it seemed to me they went faster than a horse could canter; at other times one could almost keep up by walking briskly.

SOMETHING NEW IN TIN PAILS.

GRADUATED TO MEASURE EXACTLY HALF-PINT, PINTS, QUARTS, AND GALLONS.

I THOUGHT some time ago I never wanted to see any thing new any more in the way of pails for honey; but here we are again with something newer and better—at least, that is what everybody says, and everybody wouldn't be very likely to be mistaken.

The smallest pail holds one quart when it is full, and the largest one holds a gallon when it is full, and all of them are divided by a bead in the tin, so as to show you just how much it is when it is so full. Still further, this beading is lettered, so that folks who are not very smart can tell just how much there is in the pail, by reading the letters and figures that stand under the beading. Now, I do not believe I could have been in-

THE NEW GRADUATED TIN PAILS.

duced to have started a new tin pail, if it were going to cost any more money than the old ones; but here they are, with this new graduated device, and not a cent more in the way of expense. The quart pail is 5 cts. only; the two-quart, 10 cts.; the three-quart, 15 cts., and the gallon pail only 20 cts.; and the prices by tens and hundreds are the same as those on page 21 of our price list. The pails, as you will observe, are, however, a little taller than our celebrated nested pails; and, in fact, a graduated pail can not be made to work real nicely unless it is rather tall. Now, then, the matter is right here before you, and you can do as you choose about investing in the new-fangled pails. Oh yes! when you order, just say "Novelty pails," and then you will get the right kind.

Any kind of a can or pail can be made cheaper by making the length up and down greater than the diameter: for tin can be cut to make the body, practically without waste; but in cutting the circles for tops and bottoms, a good deal of tin is wasted; and the larger these tops and bottoms, the greater the waste. Tin pails, however, do not ordinarily meet with as much favor as those about the dimensions of an ordinary tin cup; viz., with the diameter a little greater than the height.

TALK ABOUT GLEANINGS, BEES, AND DRONE-EXCLUDERS.

SOME KIND WORDS INTERSPERSED WITH VALUABLE FACTS.

GOOD MORNING, Mr. Root. This is a pleasant April morning. Please take a seat, if you can spare a few leisure moments, as I wish to talk with you. Spring time is here; the sun shines, the birds sing, and all nature begins to rejoice in praise to its Author. A more fitting time could not well be found to talk with a friend.

Well, I need not tell you I take GLEANINGS; your list of subscribers tells that. I hope you will excuse me for expressing my opinion of it to you, for it has not been formed in haste, or for the want of apicultural literature, to say nothing of nearly fifty years' experience in bee-keeping. With all this I find GLEANINGS all the more valuable.

Of course, some of the inventions and articles on bee culture are enough to make a good-natured man smile. Notwithstanding, those articles, talks, and discussions in GLEANINGS bring out some grand ideas, and much valuable information which the bee-keeper can not well afford to do without. Then your talks in *Our Homes*; you have such a clever and happy way of telling it; it must certainly meet the approbation of every good man and woman, boy and girl.

I wish every person in America, old, middle aged, and young, white, black, or brown, would turn to GLEANINGS, March 15, 1885, page 211, and read it; and those for whose special benefit it was intended should read it morning, noon, and night. Then get up in the winter at midnight and read it, till their knees would tremble like a Belshazzar; yea, even more, that the thunders and forked-tongued lightnings would flash it, and every stone, straw, stick, leaf, and tree would echo it in their ears until they are reclaimed. For, to see so many people going through the world lying, stealing, and in a heedless, lazy, slipshod, careless way, borrowing and sponging their living off their neighbors, well deserve to be treated with an ironical reception. Can they read those lines without a blush? If so, oh shame! If the ministers in the churches had the courage to preach such sermons, and try to impress it, it certainly would do much good; it is certainly one of the best sermons I ever read. I hope the reader will look it up, and see if he doesn't agree with me.

BEES.

Well, I was going to say something about the bees. Last summer there were the most bees I ever knew. Nearly all the neighbors had from one to 10 or 15, some 100 colonies. The bee-fever was running high; in fact, it was contagious; but at this writing it assumes more the nature of an intermittent; the pulse has fallen from 140 to considerably below blood-heat. Respiration is long and heavy.

Some have lost this winter one-half; some two-thirds, and some all. Alas! how soon fond expectations perish! In all my experience with bees I never knew so great a loss. It was not the cold that killed them; they died of diarrhoea. Last season the bees gathered tons of poor honey, much of it black as ink. I never saw any thing like it in honey. It had a nauseous smell, and very disagreeable taste. Some of it was so bad it had to be buried in the ground. This poor honey is what killed the bees; it gave them the diarrhoea, and they died before the winter was half over. Many

got this poor honey in the surplus boxes and brood-chamber. I put on 1000 surplus boxes, and every drop of honey in them was excellent. But in the brood-chamber there were large quantities of poor honey. I can not account for it, except that I put on the surplus boxes over two weeks later than my neighbors, and caught nothing but locust and white clover, then took them off. The poor honey in brood-chamber resulted in the loss of several colonies. I have quite a quantity of this poor honey. I don't like to let the bees have it, for fear they will retain some of it for next winter. What would you advise me in such a case?

Now, here comes another query: My bees were all on summer stands, and apparently went into winter quarters with equal chances. After this long cold winter, some of them on the first warm day in April came boiling out as if to say, "We stood the winter all right," and one colony in particular was bright, clean, and dry; not to exceed a tablespoonful of dead bees was in the hive, and the third day they were carrying in pollen.

DRONE-TRAPS.

Now something about drone-excluding devices and traps. The best device I know of is Alley's drone-trap, with my improvement attached. It is so satisfactory I see no need of anything better. On page 231 of GLEANINGS, April 1, 1885, you gave us a device from D. C. Noble, for excluding drones, which is another instance of the difference between theory and practice. It reminds me of a man who once applied for a patent to raise sheep without any wool. He says the invention is his, and calls it a drone-excluder, to be placed at the entrance of the hive, hinge side out. The doors are one-twentieth of an inch longer than the space, causing them to stand out at the bottom; and as the drones come pushing along they will raise the doors and pass out, but can not enter again.

If you remember, Mr. Root, you thought the hinges rusting might be an obstacle to the movements of the doors, and said you would be very glad to hear from some one who had used these machines. Now, I have no reason to doubt but that Mr. Noble is a nice man, and would not offer to the brother bee-keepers an article if he did not think it possessed real merit, and feels confident his device is what he claims for it; but I am inclined to think he has never given it a thorough trial. Many years ago I did not like the plan of letting the drones eat so much honey; and as soon as they could be dispensed with I frequently sat down by a colony of bees, and, with the sharp-pointed blade of my pocket-knife, I speared them as they pushed their way out on the alighting-board. After some practice I become an expert, and could take them as fast as I could count, but this took time and patience. So in 1855, nearly 30 years ago, I invented a device exactly like Mr. Noble's but made of different material. I used very heavy hard-finished paper, with fine wire hinges for the doors. One afternoon, about 3 o'clock, I placed this device on the entrance of a strong colony, well supplied with large fat drones. I sat down, folded my hands, and awaited results. Soon the bees came tumbling through the open spaces, heels overhead, then up and off about their business. After some delay I perceived a vibrating movement at the small doors; they finally opened, out rushed the drones like rats from an old barn on fire. I clapped my hands, and exclaimed, "Eureka!" But, alas! my fond expect-

tations soon vanished. Further observations convinced me that my northern laurels had degenerated into weeping-willows. When the outgoing drones opened the doors, the returning ones walked in, although the doors were so small as to but little more than admit the largest-sized drones one at a time. Bees, like some little boys, soon learn tricks, and a good many had ones too; they are as quick to learn tricks as any of our domestic animals. Well, I will tell you how they worked their cards in this case; they were very accommodating to each other; the outgoing ones turned to the right or left, as the law directs, generally to the right. The incoming ones meet them, thus keeping the doors open. Well, they have some kind of a law, like when two railroad trains meet on the same track; the one having right of way pushes the other back, and some one keeps his head in the door, thus keeping it open. Sometimes the bees open the doors, and drones pass in by them. So I never applied for a patent. Such has been my experience, and such would, I think, be friend Noble's.

JOHN W. NIMAN.

Spring Mill, 3 Richland Co., Ohio.

Friend N., you are very kind, and I am sure I thank you; but it seems to me you are a little bit rough on neighbor Noble. Although I confess that I read his article all through, eager to hear him say he had tested it on his bee-hives, and that it worked beautifully, I rather expected something like what you have mentioned. But, did not your hive have an unusual plenty of drones in it? It seems to me there must have been, or those little doors would not have been kept open for all outsiders to get in. If there are only drones enough so that each one would go out by himself, and come back by himself, it seems to me the doors must work. The outsiders will, of course, stand around waiting, and probably one going out would open a door for half a dozen to get in. But toward the close of the day, didn't the machine fence out at least a part of them? I think may be the metal doors would be less liable to the difficulty you mention, than paper ones.

A NEW PLAN OF FORMING NUCLEI,

GETTING BEES TO STAY, AND GIVING THEM COMBS FILLED WITH EGGS.

AS the time of year has arrived when most of the bee-keepers are thinking about preparing to furnish for themselves extra queens, to use in cases which occur in all well-regulated apiaries, where a spare queen is of great value through the loss of the old queen, or to supply a queen to the queenless half of a division in the swarming season, I will give the readers of GLEANINGS a new plan of forming nuclei, which I have used successfully for the past two years. On page 835 of GLEANINGS for 1884, I gave you a plan of wintering nuclei, in which I spoke of a box for shaking the bees into when wintering. The box for forming nuclei need not be so large as those spoken of there. Those I use are made by getting out two pieces, 6 inches long by 6 inches wide by $\frac{3}{4}$ thick. Also two pieces, 12 inches long by 6 wide, 2 by $\frac{3}{4}$ thick. The latter are nailed to the former, so as to form a box $10\frac{1}{2} \times 6$, inside measure, without sides. For sides I use two pieces of wire cloth, cut 12

inches long by 6 wide. One of them is nailed permanently to the box, while the other is left so it is easily removable. In the top of the box are bored two holes—a large one for the funnel (such as is used in putting up bees by the pound), and a small one through which the queen is to be put when she is given to the bees. Having the box and funnel prepared, I proceed to a colony that can spare some bees, and take out a frame well covered with bees (being careful not to get the queen), and set it down by the side of the hive, giving it a little jar, sufficient to cause the bees to fill themselves with honey, but not enough to dislodge any from the comb. If I wish a very large nucleus I take several frames, but one frame well covered with bees makes a good nucleus. As soon as the bees are filled with honey they are shaken down through the funnel into the box, when the funnel is removed and the hole closed. The frame is also placed back in the hive, when the box is to be carried to the cellar, or a dark cool room, where it is to be left for two or three hours. At this time, go to the colony from which you can best spare a queen, and take her in a cage to where your bees are in the box, when you will find them all in commotion, owing to their queenless condition. Let the box down suddenly, so as to jar all the bees to the bottom, when you will let the queen run in through the small hole with the bees. Now put the bees back, and leave over night (I generally cage the bees about 1 P. M.), when in the morning you will find them clustered and quiet, like a swarm. I now get two combs, one with honey and one having a very little brood in it, placing them in a hive, the size of which is contracted to suit by means of a division-board. This hive is placed where I wish the nucleus to stay; when I get the box of bees, remove the movable wire cloth, and shake them down at the entrance, into which they will go, fanning their wings just like a natural swarm. In two or three days more I proceed to form another nucleus in the same way, but this time I use the same queen I did to form the first, taking her out of the nucleus when I wish to give her to the bees. Thus I keep on using the same queen till I am through wanting nuclei.

Last season I made 20 with one queen. As soon as the queen is taken away, the nucleus is used the same as any queenless nucleus is. By this plan I can form a nucleus at any time I desire, and always have every bee stay where put; for after being with a strange queen over night, the bees, if any attempt to return, are treated at their former home as strangers. The nucleus is also ready to go to work at once, bringing in pollen and honey, according to its strength, the same as does a natural swarm. Again, by giving a laying queen, she lays all the eggs the nucleus can care for in the two or three days she stays, while she is kept laying all the while. I have tried using virgin queens instead of those laying, but some of them the bees will kill, while those which are not killed are a long time getting fertilized. Swarms can be made this way, and queens successfully introduced; but the chief value of the thing is in enabling one to form a good nucleus just when and where he pleases. I have been four years in perfecting it, and after testing it all of last season, and the latter part of 1883, I now present it as the best plan extant for forming nuclei in time so all can use it for the season of 1885.

16—G. M. DOOLITTLE, 40—80.

Borodino, N. Y.

Friend D., your plan is certainly sensible in many respects. This queen that you move around is, I suppose, to be the one you have selected to breed from, and, of course, valuable. During a dearth of honey it seems to me there might be some danger to the queen in introducing her so many times; but if the precautions you give are carefully followed, perhaps there will not be. You have tested it thoroughly, and probably know. Now, instead of making a cage as you suggest, why not take the usual cages we use for shipping a pound or a pound and a half of bees? These are already at hand in most apiaries. I suppose half a pound of bees would be enough to start such a nucleus, especially if they have some brood that will hatch out pretty soon. Two things contribute to prevent the bees from going back home; one is, the treatment you give them would tend to make them behave like a natural swarm; another is, that as they have a laying queen that they have recently accepted they would likely stand by her. I can imagine just how these little fellows would start out to work, if the nucleus was formed, say, during fruit-bloom.

WIRE NAILS, FOUNDATION - FASTENERS, ETC.

DR. C. C. MILLER TELLS US SOME OF HIS EXPERIENCE.

I HAVE just made an order for 6½ lbs. of wire nails of 7 different sizes. I have used a good many pounds of them in the last few years, and think I have learned something of their merits and demerits. They are very superior to ordinary nails in one respect. Where the latter will split the wood, on account of cross-grained or thin stuff, the wire nail, on account of its shape, goes through without splitting. This advantage is so great that I would not be without them; at present prices some kinds are cheaper than other nails; for although the price per lb. is greater, there are more nails in a pound, making the cost per nail less. They are excellent for clinching; you can't break them. The ease with which they bend makes them objectionable for some uses. I nailed a strip with 1½-inch wire nails for a screen-door to slam against. The constant slamming made the nails gradually bend and pull out. Common nails, on account of their rigidity, would have remained unchanged.

In their favor, it is stated that "when a nail of the old kind gets drawn out a little, or 'loose,' as we call it, it comes out very easily; but these wire nails, being all of a size, hold their whole length." From this I inferred that a wire nail would hold tighter than a common nail. The fact as stated is correct; the inference, incorrect. In spite of the fact that a wire nail holds its whole length, it takes less force to pull it out, or, in other words, a common nail holds stronger. I had hundreds of wide frames, some of them made with wire nails, some with others. In some cases where the bees fastened the bottom-bars to the tops of brood-frames, on attempting to lift out the wide frames the wire nails pulled out; the others, never. The wire nails, being smoother, start easier. In case the warping of stuff starts a nail, the wire nail will hold, after it is started, stronger than a common nail; but for or-

dinary purposes, I should say a common nail holds stronger. An objection is the difficulty of obtaining them at hardware stores; but I can always get them just right from Medina. But after all is said, I think a bee-keeper who has never tried them will be surprised to find how desirable wire nails are, and, after trial, will never want to be without them.

FOUNDATION-FASTENERS.

Heddon says he would rather have the Parker than the Clark fastener, and Mr. Gray's inventive genius has been brought into requisition to improve on the Clark. I do not wonder much at this, if the instructions are followed which are given in Root's price list. I have never seen Gray's machine, but can not imagine what improvement it can be to have the sections thrown out, unless it be to throw them into place in wide frames or supers, and I do not understand that it does this. Until I got the Clark I was well pleased with the Parker, but—just here I stopped, and went over to the shop to interview the young lady who puts in the foundation.

"Emma, give me an idea of how the Clark compares with the Parker as to ease and rapidity."

"Well, I can put in 200 starters in a day with the Clark, besides other work, and I don't know that I can put in 1000 with the Parker. At any rate, 1000 with the Parker would tire me more than 2000 with the Clark."

Then I had her try to use the Clark according to directions—"As the presser sinks the fdn. into the wood, draw one side of the section forward a little, and this drawing motion rubs the wax in the wood." It seemed to be harder, slower, and in no way better work. As she has put in a good many thousand very satisfactorily, I give herewith

HOW TO USE CLARK'S FDN. FASTENER.

Get two fire-bricks, to heat and use alternately. Common bricks will do, but do not last long, as the heat cracks them. Common flat-irons, such as women use for ironing, will do, but lose heat quicker. Lay the fdn. starters in piles in front of the hot brick before you, having the edges of fdn. next the brick, piled evenly. The edge of the fdn. should be warm enough to be pretty soft, taking care not to melt it. Give the presser a quick pressure with the feet, *letting it fly back immediately*. No "drawing forward one side of the section a little" is needed. If the starter is small, push it up straight with both thumbs before lifting the section; if large, simply turning it over may suffice; but I notice Emma deftly helps it to its place by lightly touching with the fingers of both hands in the act of turning over the section. I watched her for some minutes at her regular work when she did not know I was timing her, and she put in 7 starters per minute. I then asked her to put them in as fast as she could, and she put in 10 per minute; so it will be seen that, without hurrying, she could put in over 400 in a day of ten hours. As to the quality of the work, they are in to stay, and a good many of those fastened by the Parker dropped out.

C. C. MILLER, 200-258.

Marengo, Ills., / Apr. 17, 1885.

Thanks, friend M. A little practical experience is just what we want. Friend Clark, who invented the Clark foundation-fastener, gave the instructions we printed with it, and it has never been changed since he first gave us the machine. Very much depends on getting used to these helps, and you know how often one man decides one

way and another man another way, with precisely the same machine. We get along faster and better, we think, with the Gray machine; but may be our directions would be modified now if they were written over again.

SOMETHING GOOD FROM A RETAIL DEALER IN HONEY.

SHALL WE PUT OUR NAME AND ADDRESS ON THE HONEY WE PUT IN THE MARKET?

I RECEIVED GLEANINGS for April 1, and read with interest Mr. Hutchinson's article, and I would indorse it all with this exception: I think that, when a person has produced comb honey of No. 1 quality, he should put his name and place on each package, in a neat plain type, also the name of the honey—clover, basswood, or whatever it may be, and require his commission merchant to sell it with that brand upon it; and if he should discover that his commission merchant had scratched his name off, at once close his account with that firm, and secure another that would promise not to steal his good name. Further, never put your name or brand on any package, the contents of which is not first class in flavor, and pure as purity itself, and then ship it to the same market each year. A good name is of more value than appearance, as it will wear longer.

I have been a retailer of fruit, nuts, and comb honey for 15 years, and know that, in fruit, the good name of a shipper is valuable. The tradesman finds out shippers that are reliable. There are several shippers of berries and peaches in Delaware whose name will sell their goods in the Boston market quick, at full prices, when others have to wait to be inspected. Why? Because they have never tried to make their goods look better than they were, and the buyers have found it out. Their seconds are sent to market without their name, and sold on the merits of the article. I have seen wagonloads of crates of strawberries and blackberries sold, when the market was quick, without being opened, the buyers engaging simply by the name of their favorite shipper. Why can't it be so with honey?

There is a lady in Vermont who makes maple sugar, and has sent it to one firm in Boston for the past five years. Every box is engaged before it gets to Boston, and we have to pay from 3 to 5 cents a pound more than common maple sugar sells for, and are glad to get it.

Friend Root, you, on page 239, hit the nail on the head where you say, "When you want to buy honey, or any thing else, be sure that a good man's name is on the label." And here I want to say a word for R. Wilkin, of San Buenaventura, Cal.; for on page 173 he seems to be feeling badly. Tell him to cheer up, and continue to send California extracted honey like this last lot in quality, to the Boston market, and he will surely reap his reward, for there was never any other nearly as good here before. I bought one can of 60 lbs. to try, and am now on the tenth can. Every one whom I have induced to try it has liked it very much, and a consumer always remembers where he got a nice article, and comes again.

One more for Brother Hutchinson. On page 256 he closes his article thus: "But, says some one, we can not get so much honey per colony when it is stored in sections as we can in frames. Beg par-

don, my friend; that is simply because you don't know how." Brotherly love requires the educated to instruct the ignorant. Please tell us how to do it. I am willing and anxious to learn; don't be afraid that you will overstock the market; lower the price five cents per pound; and four times the quantity can be sold. I have retailed 2500 lbs. of honey this season. CALVIN W. SMITH.

Wellesley Hills, Mass., Apr. 12, 1885.

Friend S., I did not understand friend H. to say that the producer's name should not be on every package. I thought he objected to a large-sized placard. I entirely agree with you, that the producer's name ought to be on every thing he sells, as far as practicable; and even were I going to buy eggs I should like to know where they came from. Stoddard, in his little book called "An Egg-Farm," says that a wagon should be run to the towns adjoining, delivering fresh eggs the day they are laid, or, at least, the day after; and I think he is right in saying that eggs so delivered would bring a cent or two more a dozen than those bought at the groceries. Only a few weeks ago, before our hens began to lay, one of the children was sent up street for some eggs. A part of them were bad. The one who took them to market doubtless knew they were bad; at any rate, he did not *know* they were good; and in either case I should like to know who did it. We are in the habit of paying a cent or two more for butter when we are sure that a certain individual made it. I do not know why this should not be the case with comb honey. With extracted honey it would certainly be of the greatest importance to know whom it came from. We have the same state of affairs in maple sugar and maple molasses. Sometimes a clerk will come up, saying, "There is a man here who wants to sell you some maple molasses."

"What is the name?"

"Why, it is Mr. —."

"Tell him we do not care to buy any to-day."

Now, friends, had the clerk mentioned some other names that I know well, I would have gone down to see the molasses at once. Yes, we have those whose name would be such a guarantee that I should be safe in telling the clerk, "Tell him we will take all he has got." Now, my friend, are you one of that sort of people? Our new potato-book has some grand thoughts on this very subject.

WINTERING.

SOME SENSIBLE SUGGESTIONS IN REGARD TO OUR RECENT LOSSES.

WE ALL can now look over the wreck of the past winter and count our losses. We are so used to the remark, "My bees all dead; how are yours?" that we scarcely expect any thing else. The fact is, there are but few left in this locality, except with those who use a chaff hive, and in these the loss is from 25 to 50 per cent.

I had 55 colonies last fall in excellent condition; now have but 40, which is not so bad, being the lowest percentage of loss in this neighborhood, so far

as reported. Yet this is my first loss since I commenced bee-keeping ten years ago. My theory for wintering has been, plenty of bees, plenty of stores of good food, and a good chaff hive. These conditions were all present last fall; but it seems something was still lacking to meet the extreme cold of last winter. Most of those dead colonies perished of starvation, having consumed all the honey in the combs on which they were clustered, and with a thermometer scarcely above zero; for two weeks in March they were unable to change their location in the hives, although winter-passages were at hand. My past success in wintering made it a matter of indifference about reducing the space below the ten frames by a division-board, except an occasional weak colony. One such came through the past winter, on six frames, in good condition. Had I reduced all to the same space, what would have been the result? Will those who have been practicing the division-board system report your percentage of loss, with the particular condition, that we may get an idea of its real value?

Observation shows, that before an extremely hard winter the bees do but little swarming, instinct teaching them to hold their strength to meet the rigor of winter; also that a disastrous winter is followed by a summer of unusual activity in the bee-yard, a seeming effort being made to recover the winter losses. Such I predict the coming summer. Let those of us who are more fortunate share with the less fortunate—at swarming time—at reasonable prices, that all who wish may utilize those empty hives and well filled frames.

J. NEWTON WHITE.

Grove City, Mercer Co., Pa., April 9, 1885.

THE HEDDON HIVE.

17 $\frac{1}{2}$ AND 17 $\frac{3}{4}$ FRAME.—LIABILITY OF COVERS TO BLOW OFF, ETC.

FRIEND ROOT:—You say in GLEANINGS, page 215, that great confusion is going to result because friend Heddon uses 17 $\frac{1}{2}$ instead of 17 $\frac{3}{4}$ frames. Why can't your customers specify which frame they want? It's just as easy to make the hive for 17 $\frac{1}{2}$ as 17 $\frac{3}{4}$. The honey-board can be made longer; and by using $\frac{3}{4}$ -inch instead of $\frac{1}{2}$ -inch thick pieces on end of super, you can make the super as long as the hive.

Dr. Miller is dreadfully worried about that 15-lb. stone. Now, doctor, you are worrying yourself for nothing. The cover, if rightly made, needs nothing to hold it down. I have used them, and never had one blow off; and they have been through some pretty hard storms too. In my opinion, a wind that will take the cover off will move the hive too. I have seen large covers made the same way, and was told that they never blew off. That 15-lb. stone is to keep the shade-board in place, which being 2x3 feet, presents considerable surface to the wind. And, doctor, have you been out of practice so long that you have no remedy for backache? I use the Heddon system adapted to 17 $\frac{1}{2}$ frames, and think that is the best out. I use 17 $\frac{1}{2}$ because I commenced using it when I first commenced, and don't want to change. Those that are so loth to take hold of the Heddon system will be well satisfied with it, unless I am greatly mistaken.

The past winter has been an extra severe one for bees in this section. Out of 27 stands packed on

their summer stands, 18 are dead, one more will die, if not more. Yet I don't consider myself in Blasted Hopes, but will try again. E. L. MASON.

Hillsboro, Wis., April 7, 1885.

In regard to the 17 $\frac{1}{2}$ frames, friend M., the 17 $\frac{1}{2}$ are always in stock, and all the appurtenances belonging thereto. In fact, we keep a great warehouse full of hives and frames and other fixings. Now, should we build another great warehouse and keep that full also, that we may be ready to fill orders for either kind? Again, nine-tenths of our customers order Simplicity frames and Simplicity hives, or Langstroth hives and Langstroth frames, without saying any thing about dimensions. What kind should we send them—write back and inquire, and possibly have them so vexed by this amount of delay that they will countermand their order? Then, again, suppose one wants to buy and sell hives and fixtures. Starting off on a shorter hive and shorter frame would be a national calamity. If you want to see how it works, try it, and it will not take many years for you to declare you won't have any thing about you hereafter that is not conformed to the regular standard goods in common use by the majority of bee-men. The Heddon eight-frame hive is going to make trouble in the same way, to some extent; but if they are made to hold a standard frame, the trouble will not be nearly as great. I have sometimes really thought that it would be a kindness to refuse to make or encourage the making of any thing different from the standard goods. The veterans can use what they like; but for beginners to get a notion in their heads that they want something a little different, is a great misfortune. If nothing but staple goods are to be had, at moderate prices, it would do much to end these troubles with things that won't fit or work together.—I presume that we shall have to give up, that the Heddon covers do not blow off, since so many declare it is a fact.

A WORD IN FAVOR OF QUEEN-CLIPPING.

A SUGGESTION IN REGARD TO THE MATTER, FROM OUR GOOD FRIEND MRS. JENNIE CUTP.

IN your last issue, April 15, you say you believe the general opinion is that we do not want our queens' wings clipped; but "I am afraid to say so." Now, Bro. Root, I do hope, for the benefit of lady bee-keepers, you will continue to be afraid to say so. I have practiced it so successfully the three years I have been in the business, that I must say I favor it with both hands up; in fact, I will not tolerate a queen in my apiary unclipped, if I know it. I believe it is generally conceded that it does not injure her, but only mars her beauty. Of course, it necessitates keeping tidy around the front of the hive, so she can be readily found when a swarm issues. For me they seldom get more than a foot or two from the entrance, and I have never lost one yet. Just think of the advantage. No nervous excitement for fear your swarm will leave. Just pick up your queen, put her in a cage, move the hive the swarm issued from back a foot or two, cover it with a table-cloth, place the new hive where the old one stood. When the swarm gets tired waiting

for the queen to join them they will come back and enter what they suppose to be their old home. While they are passing in, release the queen and she will enter with them; then carry them where you want them to remain; put the old hive back in its place, and the work is done.

If there is no one to assist you moving hives, tie your queen-cage, with queen in it, to a pole, and they will cluster around it nine times out of ten, and you can carry them to the hive without assistance. Clipped queens for me, every time.

Hilliard, O.

JENNIE CULP.

HEDDON'S ARRANGEMENT.

COVERS WITHOUT ENAMEL SHEETS, ETC.

AS to friend Snow's article in GLEANINGS for April 15, page 275, I'll venture to say that he never saw a Heddon hive or a Heddon crate; or if he did, never used either. As to the cover, it suits me "to a letter;" don't want any "telescope" hives around me.

On page 274, same number, at the close of the first article, you say that you would like to look through Heddon's apiary and see if he or his students did not mash hundreds of bees when they placed the cover back on the hives in a hurry. Now, if you can't imagine how to put on a board cover without smashing bees, I will try to tell you. Simply place one edge of the cover on one corner of the hive; now shove the cover over the hive as quick as you have a mind to; not a bee will be killed, for the edge of the cover will brush off all bees on the edge of the hive; no smoking all around the edge of the hive, to drive the bees off. They are cheaper, cost less, and are easier to handle than the kind you use.

I have seen hundreds in actual use, but never saw one (that was properly made) that had warped enough to admit a bee under it. Even if they do kill a few bees, I think that the time wasted in bothering with a cloth or any kind of a mat over the frames is worth more than the few bees killed.

As to that hibernating business that Mr. Doolittle speaks of, I will say that it is no use trying. I have tried the same thing that he has, over and over again, with honey and without honey, and every other way, but they would not survive after a lapse of fifty or sixty hours—no use. I think that Mr. Heddon has "hit the nail right on the head in regard to wintering."

BEE.

Malone, N. Y., April 18, 1885.

Friend B., we do not, as a rule, publish letters with no name appended. Of course, we withhold the name where the party desires it, but your letter was sent without any signature whatever, except the one given above. By the way, it seems to me your remarks to the editor of your bee-journal are not very respectful, where you say, "If you can not imagine how to put on a board cover," etc. It has often been said, if you have no respect for the man, courtesy dictates that you should show respect for the office he holds. Before bee-journals had an existence, Langstroth hives, and many others, were made with a cover to slide over the top, as you suggest, and they worked beautifully without any bees in the hives. Yes, they did well for the first season, perhaps, or until fall; and in localities where propolis was not plentiful, *may be* they did well year after

year. But our bee-keepers of Medina County, and I guess a great part of our Ohio bee-keepers, will likely smile when they read your directions as given above. Our bees go to work, and cement their cover down tight with propolis. Sometimes they put it on so thick that it runs down inside of the hive, even filling the rabbets, and they seem to be especially fond of daubing great quantities around where there is a joint, such as is made by laying a smooth board on top of hive. Well, with both cover and the top edge of the hive plastered up with this propolis, *sliding covers* on is rather up-hill business. I have covered hives hundreds of times in the way you indicate; for before the Simplicity hive was given to the world, it was the only way we had of doing. I do not know but I shall have to take a trip up to Michigan, expressly to see some of the brethren handle Heddon hives without killing bees. I think I should prefer bothering with the cloth or mat, however, rather than see my bees killed every time the hives are opened.—In regard to Friend Snow's criticism on page 275, I admit that it is hardly kind or courteous; and, by the way, it impresses me just now that I have been allowing almost too much liberty in this direction. Now, friends, if it becomes necessary for us to criticise, can we not all try to be a little more friendly about it, and show a little more of a Christian spirit?

NOTES FROM THE BANNER APIARY.

NO. 65.

HOW THE BEES WINTERED.

LAST fall some of our colonies were given sugar stores in whole, others in part, while others had wholly natural stores. Twenty-five were in chaff hives, with the additional protection of manure banked up around them. Twenty-four were packed about one foot thick with hay, sawdust, and forest-leaves. Eleven were buried in a clamp, and 33 placed in the cellar. Of those in the chaff hives, five are alive. Some of those that died perished of diarrhoea, and the others show no signs of this trouble: they are "just dead." Of those packed in dry leaves, *every one* is dead; a few show *slight* traces of diarrhoea, but the majority are *simply dead*, with clean, dry combs of sugar stores. With the exception of one colony, and that starved by getting over to one side of the hive, the bees in the clamp came out bright, clean, dry, healthy, and strong in numbers. They have wintered the most perfectly that I have ever seen bees wintered. In the cellar, 8 colonies have perished, some of diarrhoea, and others showing no symptoms of it.

One fact stands out beautifully in bold relief—not a colony with nothing but pure sugar stores has perished from, or showed a symptom of, *diarrhoea*. I have noticed this ever since I began experimenting with sugar stores. Last year, when I lost nearly 60 colonies in a clamp, *not one* with sugar stores showed any symptoms of diarrhoea. At last, we have that arch fiend, diarrhoea, under our foot! Having conquered this enemy, we find, however, that there is *another one*. Mr. Heddon says his name is Jack Frost. This we are not yet prepared

to accept, nor yet to reject; but it certainly appears reasonable that he bears this cognomen. One thing is certain: Jack thrust his ugly phiz into our cellar, and glared at us several times last winter.

I have not seen a more graphic account of the severity of the past winter than one that I read this morning in the *Rural New Yorker*. It was written by Chas. W. Garfield, the genial secretary of our State Horticultural Society. I quote as follows: "We have had a terrible winter. Peach-trees on my place are killed; tender varieties of apples discolored; all raspberries and blackberries killed to the snow-line; plum wood is injured. I went into the woods to see how the oak grubs stood it, and found the young twigs on last year's growth in low places materially injured. I have not examined fence-posts yet, but it must have been 'tough on 'em' in the hollows." As Prof. Cook remarks, in an excellent letter in the same number of the *R. N. Y.*, "What is packing in such a winter as this?"

Well, my friends, *packing*, or *something*, has again enabled "Cyula Linswik" and her sister to successfully winter their entire apiary of 61 colonies. Please don't say it is locality, because nearly all the other bees in that vicinity are dead.

The majority of our 40 living colonies are, apparently, healthy, and strong in numbers. It seemed to be something like this: If a colony was going to live, it lived; if not, it died; there was no gradual dwindling away; every colony that was strong and healthy the middle of the winter has remained so.

I must thank Prof. Cook for his criticisms of one year ago upon my articles in favor of burying bees in clamps. Had it not been for this light touch of the spur I might not have buried any bees last fall. I will confess that I did not bury the bees because I expected them to winter any better than *any* of my bees, but rather to add another example to the number that are necessary in making a real demonstration. I expect to eventually adopt cellar wintering, not because bees can not be as successfully wintered in clamps, but because it involves less labor.

KILLING BEES WHEN PUTTING ON THE COVER.

I fail to catch your meaning, where, on page 214, you infer that Mr. Heddon or his students smash hundreds of bees when they place the cover back on the hive in a hurry. If you should raise a Simplicity hive off the bottom-board, and then replace the hive, would you kill many bees? I think not. The cases are almost parallel.

FIXTURES VS. DISPLAY.

I do not agree with Mr. Snow, on page 275. A description of fixtures is of more importance than a description of some honey-show. Of what *real* benefit is the latter? And why does Mr. S. indulge in such a *fling* at the Heddon fixtures? Has he tried them, and does he know what he is talking about?

THE CONTENTS OF BEE-JOURNALS.

Mr. Smith, on page 266, very nearly expresses my ideas in regard to the contents of bee-journals. If a journal is going to be a bee-journal, let it be a bee-journal, and not a mixture of bees, religion, strawberries, poultry, carp, silkworms, rabbits, tobacco columns, smilies, growleries, etc. I do not object to a discussion of any of these topics, if it is done in the proper place; but I do not consider a bee-journal the proper place in which to discuss them, and I have heard many others express similar views. If GLEANINGS could only be filled with such articles as those given us in the last two num-

bers, by Mr. Doolittle, Prof. Cook, Dr. Miller, and Mr. Heddon, it would tower head and shoulders above its competitors. Perhaps it would be as difficult to receive a sufficient number of such valuable articles to fill GLEANINGS as it would to induce its editor to make the desired change; and we shall probably have to try to be satisfied with GLEANINGS as it is, and thankful if we are allowed the luxury of expressing our opinions.

S. - W. Z. HUTCHINSON, 68-41.

Rogersville, Mich., April 17, 1885.

Friend H., I am very sorry to hear you have lost again so heavily, and yet I am glad to see you come out and own up as usual. Was it not the extra care that Cyula and her sister gave their bees that brought them through the winter so safely? Do you know what troubles we have had in wintering *our* bees? Well, lately we have had little or no trouble, and it is, in our opinion, and in *our* apiary, only a matter of careful preparation. Now, why your bees should die when I am quite sure you gave them this careful attention, as well as the rest of us, is something that stumbles me; I can not understand it. Cellar wintering in our locality would probably be a saving of stores, but I can not think it would give better results otherwise than we get with our chaff hives.—In regard to killing bees when putting on the covers, I replied to this in another column. We can not raise a Simplicity hive from the bottom-board, and put it back, without killing many bees, yet the Simplicity hive has the bottom edges narrowed down to almost a knife-edge, as you are probably aware. Whenever we raise the Simplicity hive from the bottom-board in warm weather, hundreds of bees immediately cover it on all sides. If it were as light as the cover, by taking pains we could induce them to get out of the way; but a hive full of combs always crushes more or less. Of course, it can be slid back and forth to open and close the entrance; but this propolis we have spoken so much about greatly hinders this operation, and requires the use of a long screw-driver as a lever very often to get the hive even started.

Perhaps no other apiary in the world of its size has bees handled as much as ours are handled, for we raise more queens than any other apiary in the world, if I am not mistaken. Well, I am glad to be able to say that we handle our bees without killing them, even if a man's time is worth more than the bee's life; and if any of the brethren or sisters can take out more queens and send them off in a day than we do, we shall be glad to see them, or have them call and see us. I thought of this when I read what some of the brethren said about the metal corners.—Friend H., GLEANINGS is not devoted *entirely* and *exclusively* to bees. If you look on the cover you will see "Peace on earth, good will toward men," standing out over and above the bee on the wing; and, God helping me, this little motto shall stand over and above all other things on earth so long as God gives me strength to manage business. Whenever I think "peace on earth, good will toward men," can be better enhanced by bees, strawberries, poultry, rabbits, or tobacco, I shall take them up

without being troubled. GLEANINGS has never lacked patronage since the Home Papers were started. In fact, the calls from almost all quarters of the earth on my strength and time have often seemed as if they would overwhelm me; and, may God be praised that I have been enabled to be of use to the brethren; and I thank him a thousand times more for the great privilege he has vouchsafed to me, of being enabled to lead at least a few souls toward the path of eternal life, than that he has prospered me in furthering the cause of bee culture. There are plenty of bee-journals that do not feel called upon to "mix things up," as some of the brethren are pleased to term it. Why not give them a lift, in place of finding fault with the way GLEANINGS is managed? I am sure I am glad to see them prosper; and sometimes, when I feel specially overburdened with a multitude of cares, I have felt as if I would gladly and willingly divide with them a portion of this great amount of business that needs doing by some one.

STORING EXTRACTED HONEY.

HOW SHALL WE MAKE A TANK OF SUFFICIENT CAPACITY TO HOLD A COUPLE OF TONS?

COULD you tell me, through your journal, how to build a honey-tank? A short article will do—one to hold two tons of honey. Don't put this in the waste-basket, as it is important. Decatur, Texas. JOSEPH ROSS.

A tank to hold two tons of honey would have to hold about 364 gallons, or as much as eight of the largest-sized barrels. Inasmuch as such a receptacle could not well be moved, I should advise putting the honey into cans or barrels; but if the circumstances are such that you really must have a two-ton tank, perhaps your cheapest way to make it would be like our wooden cisterns. In New Orleans all the water that is used is kept in these big tubs, or tanks, and they all stand on top of the ground. But, another thing comes in here: I think it is somewhat doubtful if honey can be stored any length of time in a wooden receptacle, without becoming tainted. Galvanized iron is also objectionable, because the acid of the honey dissolves the zinc. It may not be perceptible unless a little honey should be left standing some time over quite a surface of the galvanized iron. In that case it becomes poisonous, and I would not use galvanized iron for containing honey at all, not even for a honey-extractor. Now, then, what shall we use? I do not know of any thing better than a tank of wood lined with tin. Fasten the tin on to the wood with nails coated with tin, and then solder the heads fast to the tin, using nothing but rosin for doing the soldering. The rosin must then be cleaned off carefully, or that would taint the honey. I believe, my friend, before you get through you will conclude that a waxed barrel will be cheaper, and it is also ready for shipment when you want to ship. I might mention, by the way, that the nicest honey we have ever received from California, or anywhere else, comes in the

square tin cases, cased two in a box, each can holding about 60 lbs. Hadn't you better put your honey into these tin cases? If you want a tank to ripen it, however, I would make it of plank, and cover it with tin in the way I have suggested. Very likely some of the readers of GLEANINGS can give us some hints in this matter. I should like to hear from friends Wilkin, C. F. Muth, Poppleton, and others, who handle extracted honey in large quantities.

THE OTHER SIDE OF CALIFORNIA.

IS IT ADVISABLE TO PULL UP STAKES AND GO THERE?

FRIEND ROBT:—I wish to make a few remarks on friend Gallup's article, p. 236. I agree with him in all that he says, with the exception of the last paragraph of his letter. One might be led to think, from what he writes, that a person could make a living here, with a small capital and little or no work. I think that friend G. has done wrong in stating the matter as he did; and for fear that some may come here and be disappointed, I will give a few facts and figures.

California has been painted too much on the bright side, and the result has been that people have flocked here, only to find things different from what they expected. Being among strangers, in a strange land, they become homesick and disgusted, return east, and give California a bad name; whereas, had both sides of the view been presented for their consideration, and plain truths told them, they would have known what to expect, and have been better satisfied and contented upon their arrival here. If one wishes to come here for his health, I say come, as I think that this is the finest climate on earth; but if one comes here to make a living, I would advise him to come with more than \$500—yes, or twice that amount. And right here I will say that there is no place on the face of the earth where there are more days of *hard* work done in a year, than right here in California. Good fruit-land is worth from \$75 to \$200 dollars an acre, with no improvements; lumber, from \$35 to \$47 per M.; trees, each, apricot, 25 cts.; prune, 20 cts.; apple, 30 to 40 cts.; cherries, 40 cts.; oranges (budded), 50 cts. to \$1.00. Provisions are about the same as in the East; some few things are a little higher. Now let me ask, How much land, what kind of a house, how many trees, would \$500 pay for, to say nothing about the necessary tools, stock, and household goods, and a person's living until the orchard comes to bearing?

As to our big crops of honey, whether you brother bee-keepers across the Rockies believe them or not, they are facts; the following are from my report of 1885:

Mr. F., number of stands, 70	average per hive, 623 lbs.
" M., " " " 200	" " " 400 lbs.
" J., " " " 29	" " " 275 lbs.
" S., " " " 50	" " " 320 lbs.

But for all this, it is not all plain sailing here in keeping bees; it has its drawbacks as well as in the East. One trouble is, the "off years," when bees make no honey at all, and have to be fed or starve; and in the last few years these "off years" have become quite common; and then, foul brood is becoming the curse of this range of mountains (Sierra Madre). There are few apiaries that are not affect-

ed with this disease. Yet for all these drawbacks I would not take, as a gift, and attempt to keep bees, if one would give me the best apiary in the most favorable locality, east of the Rockies. The greatest trouble that I see is your cold winters. I do not believe it possible to winter bees successfully *every* time in such a cold locality, as bees will not live in confinement so long and be healthy.

Duarte, Cal., April 13, 1885.

W. W. Bliss.

HIBERNATION.

DO BEES HIBERNATE, OR DO THEY NOT?

DEAR MR. EDITOR:—Doubtless you have noticed the just flagellation which I receive from our good friend Clarke, in *A. B. J.*, Apr. 8. Of course, I ought to have said, "In my judgment, bees never hibernate." Let me add right here, that I do not plead guilty to all the harsh sayings I am credited with. I mean *always* to be courteous. Reporters at conventions must be brief, and so they often give our assertions a sharp twang that we are not responsible for.

Hibernation, I understand, to be like sleep, only far more profound and persistent. In this state, respiration is greatly reduced, the temperature falls nearly or quite to that of the surrounding air, the heart beats very feebly, and has power, through heightened irritability, to circulate impure or venous blood. The animal, when hibernating, takes no food; is torpid, and hard to arouse. In real hibernation there is no emission of fecal matter. Was not the fecal mass you saw in Mammoth Cave the droppings of bats in summer? Most insects do hibernate; indeed, so profoundly that all respiration and circulation are held in abeyance. Indeed, to answer your question in last GLEANINGS, I have had caterpillars frozen to the condition of an icicle, and yet, with warmth, revive and seem all right. De Geer, Reaumur, and Kirby, all record the same startling fact.

Now, how is it with our hive-bees? The organs of the mammals, in hibernation, are as cold, often, as the surrounding air. I have found, by putting a thermometer into the cluster, that in the case of bees the temperature will always range from 26° F. to 36° F. above the outside cold in winter. In severe weather there may be a difference of from 6½° to 86°. We thus see that the vital action of bees does not fade out, and, of course, the mainsprings of this action, the heart and respiratory organs, do not greatly lessen, or, much less, fade away. Bees also take food, are constantly changing their position, and are easily aroused. I do not believe that bees can be taken at any time, unless fatally or seriously chilled, and the cluster be broken, in a warm room, and they not show full activity. Therefore I repeat, I do not think that our bees hibernate. The great Kirby, of England, is in accord with this. He says bees do not hibernate (see *Ency. Brit.*, Vol. II., p. 787).

BACTERIA, ETC.

Please allow me to correct a statement in Mr. Heddon's excellent article, April 15, p. 270. "Prof. Cook thinks it (nitrogen) may be taken by consumption of bacteria by the bees." As will be seen by my own article, this is not my view at all. Either my hasty composition, or poor writing misled Mr. Heddon. There is no ground for such a be-

lief. The presence of bacteria makes the presence of nitrogen probable, if not absolutely certain. In this disease, diarrhoea, the bacteria seem always present, whether as a cause or simply as an attendant, I know not. The spores (bacterial seeds) are ever present. With the right conditions they germinate, and the bacteria and consequent putrefaction occur. Perhaps the bacteria cause all the trouble. Perhaps they find a suitable feeding-ground or breeding-place in the diarrhoeic matter of the intestines. A. J. Cook.

Lansing, Mich., April 18, 1885.

Friend Cook, if you will excuse my frankness, I do think you sometimes omit the phrase, "In my judgment," or "According to my experience." At the convention in Michigan I felt like protesting a little because you so flatly disputed friend Doolittle, although the proof you gave seemed satisfactory to me that he was wrong and you were right. In thinking of the matter since then, I have wondered whether the circumstances were not sometimes such that we are excusable for making positive statements. Some time ago a man came to see me, who had a patent on a hive, and the hive did not even embrace movable combs. He made some statements that were so very far out of the way that I flatly contradicted him, in the presence of many others. He suggested that *that was my opinion*. I told him there was no opinion about it; that what he had been telling was untrue, but that I did not know whether he uttered the untruth through purpose or through ignorance. I felt a little sorry I had spoken so, but the case seemed very aggravating. A few days afterward I was told that the man was *crazy*. Now, we who have been discussing this hibernation theory are none of us *crazy*; at least I *think* we are not (you see I am learning already to beware of being too positive). I have always felt sure, friend Cook, that you intended to imply "in your judgment," even though you neglected to say it.—Permit me to thank you for your explanation in regard to the droppings of the bats. It was a puzzle to me at once to see how they could accumulate guano, and hanging there apparently lifeless (until one took hold of them) for so many months in the year. I suggested that perhaps they were in full flesh when they go in in the fall; but your solution is doubtless the correct one.

By the way, can a thermometer be introduced into a cluster of bees without raising the temperature so as to spoil the experiment? I think I have broken clusters of bees, where they were not seriously chilled—in fact, not chilled at all to harm them—when they acted as if they were dead for as much as—I was going to say five minutes; but as I did not think to note the time at all, may be it was a much smaller portion of time. As I said before, they were tied up together in a hard knot, and it seemed as if it would pull their bodies to pieces to break this knot open before they were warmed up so that they could untangle themselves of their own accord. I should be inclined to think with friend Clarke, that bees sometimes go into a state that is about half hibernation.

A COVER FOR EXTRACTORS.

A SURE THING ON PREVENTING HONEY FROM FLYING OVER.

MY extractor was bought in 1874, and was a rather crude affair, judged by the "standard of excellence" which obtains at present. By strengthening some of the weak points it answered the purpose for several years; then a change from the "standard" to the L. frame necessitated a change in the internal arrangements of the extractor; and as those solid sheets of tin that were used in your first extractors had been denounced as the cause of honey flying over the top of the can, I made a new revolving frame after the manner of the latest style of constructing that article. I supposed that I would not again be troubled with threads of honey flying through the air to a distance of three or four feet in every direction, but the can was rather low for the L. frame; and when it came to thick honey, the annoyance was so great that I just stopped the machine, with the determination to let it stand till I could devise some way to stop the fine threads of honey from sailing over the top of the can.

Work in the apiary was pressing, and something must be done at once. With the view of providing a temporary bridge for the emergency, I borrowed a square of muslin from Mrs. R., took off the large cog-wheel, cut a slit in the center of the square of muslin, to let the small cog-wheel and the standard for the large wheel pass through. Now, when the muslin was drawn down nicely over the top of the can, with the small gear-wheel, and the standard on which the large wheel turns, projecting above the muslin, a twine string was drawn around under the iron hoop, over the muslin for half the distance, and then passed through holes punched in the muslin, and continued around under the muslin, and tied. When finished, one-half of my muslin cover was held securely in place by the twine while the other half was loose and could be opened and closed more quickly, perhaps, than any other kind of cover that has been used. The muslin prevents the current of air, and there is no honey thrown against the under side of it; and after using it several years I am so well satisfied with that plan of keeping all dust out of the can, and all the honey in it, that I would not willingly do without it or exchange it for any other kind of cover I have seen.

East Springfield, O.

R. M. REYNOLDS.

From your description, friend R., I presume the usual cloth cover we send out with our machines could be used in the same way, by making a hole in the center for the small gear-wheel to pass through. The cover will then need to be fastened with a cord, so that the rubber band may be drawn back, uncovering just half of the top of the can. This permits the combs to be put in and taken out, and is very quickly put back in place. None of the extractors we send out now are faulty in this respect, I believe; but those from other makers, and those we made some time ago, may be quickly fixed on the plan friend R. mentions. It seems to me it would be quite a hindrance, to be obliged to uncover part of the extractor, however, every time we lift out combs or put them back, and I should much prefer an extractor made so no cover of any kind would be necessary to keep the honey from flying over.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

PYRACANTHA, BEES, ETC., IN GEORGIA.

IN a recent issue of GLEANINGS you call for information as to the value of pyracantha for bees, etc. At Griffin, Ga., pyracantha grows to the height of from 8 to 12 feet, and flowers in profusion in the spring. It is much frequented by the bees, but I don't know whether it is for pollen or honey. I will watch more closely this spring, and ascertain. Pyracantha is a perfectly healthy bush, and makes the best hedge for the South. Our spring opened a month later than usual this year; and the result is, the bees have had a hard time. The apple is now in bloom, and every thing will now move off nicely.

Griffin, Ga., Apr. 21, 1885.

W. E. H. SEARCY.

BUYING OLD COMBS TO RENDER INTO WAX, ETC.

The farmers around here have lost much over half of their bees. Last year's swarms nearly all died. The principal cause is starvation. Only a few of the earlier swarms stored enough to live on.

I have recently learned a lesson. Experience taught it me in a way that I do not want it to do again. I bought up a lot of old comb to render into beeswax, paying from eight to ten cents per lb. for it. I found it lost two-thirds in rendering. That is, I paid about 30 cts. per lb. for it, besides the investment of time and labor, when I may not get 30 cts. for it.

DAMP CHAFF CUSHIONS.

My chaff cushions are covered on the under side with cloth. They will get wet and moldy sometimes from necessity. I can not take them off and dry them every time they get wet in the winter. Now, is that moldy or rotten chaff as good a non-conductor of heat as that which is dry and fresh?

Finally, I should like to put myself on record as one in hearty sympathy with your position on tobacco. Before I ever heard of GLEANINGS I was a temperance, prohibition, anti-tobaccoist, and it delights me exceedingly to find a journal, not specifically devoted to morals or religion, *sitting down* so hard on the weed, and all such dirty indulgences.

Mechanicsburg, Ill.

GEO. F. ROBBINS.

Thanks for your report about the wax, friend R. The question has come up several times, as to how much one could afford to pay for empty combs. We have tested several lots, and find it varies a good deal in the amount of wax yielded. New combs and cappings will give perhaps from $\frac{1}{2}$ to $\frac{3}{4}$ parts of wax; but old heavy combs often do not give more than $\frac{1}{4}$. Our plan is to decline purchasing, but tell the friends we will try out their old trash for a cent a pound, and sometimes the time spent makes it a losing business even then.—I am inclined to think the dampness is caused by the extra cloth covering on the under side. Since we have adopted the coarse burlap as a material for making chaff cushions, we have been much pleased to find the dampness pretty much all done away with. The idea is to get something as near like loose chaff as possible, and this burlap is so porous that the air goes right through it, drying out any moisture that may accumulate during severe zero weather. I should say that the moldy or rotten chaff would not answer at all.

WHAT THE PEOPLE SAY.

This beautiful April morning I feel in some respects as did Mr. Waldo, of Quincy, Ills.; not on account of my loss in bees, for I have succeeded in wintering two colonies out of three, while I know of some who have lost nearly their entire stock, but on account of the remarks of other people, such as, "What makes you fuss with your bees so much?" "you fuss with them so much they never will amount to any thing;" "they are a nuisance to you;" "you never will make any thing from them." And when I lose, which is quite frequently, they will say, "There, I told you so," and all such like remarks. Instead of helping a fellow by some word or suggestion, most of these remarks come from people who don't know a queen-bee from a blue-bottle fly. Perhaps you have traveled over about the same road that I am on now; if so, you know something how I feel. No one ever had a more genuine love for the business than I. I have been keeping bees eight years, and now have only two colonies, and have spent at least, for labor and material, \$150. If I must give up the business it will be with many misgivings. Probably this will find its way into the waste-basket. If so, of course that is the place for it. B. H. BRADLEY.

Eddyville, N. Y., April 17, 1885.

Friend B., may be some of these remarks come because you have been telling too much what you are *going* to do with the bees. Now, just stop telling, and go to *doing*. When they make such unkind remarks, reply pleasantly and mildly; own up that the business is somewhat risky, if need be, but let your acts speak instead of words, and by and by you will find that your neighbors are all standing by your side, and quoting you, and feeling proud of having so enterprising a man in their midst; that is, if you persevere until you become master of your chosen avocation.

He that tilleth his land shall have bread; but he that followeth vain persons is void of understanding.—Prov. 12: 11.

SAVING THE SEED FROM BORAGE.

How do you save the borage seed? Our bees have wintered well. I lost but one swarm out of 30, and they were smothered.

R. H. MILLER.

Akron, Iowa, April 9, 1885.

Friend M., it is a slow process, the best way you can fix it; for the seeds are ripening every day for a period of many weeks. The way we do is to take a large sieve, bend over the plants when the seed is ready to jar out easily, then strike the plant with a little stick or paddle. The size of meshes of the sieve should be such as to let dust and rubbish pass through, but not the borage seed. When you have been clear over your borage patch, take another sieve that will just permit the seed to pass through, then you will have it tolerably clean. Passing it through a fanning-mill afterward, however, will make it still better. I know this is some trouble, but it is the only way to manage with seeds that ripen day after day for a long while, like borage, spider flower, Simpson, and most of our honey-plants. The difficulty of gathering them is one reason why many of these seeds can not be furnished at a lower price.

SAD AND SUDDEN DEATH OF ONE OF OUR BEE-FRIENDS.

I was called yesterday to look at the apiary of J. H. Struberger. You know him somewhat, as he has been taking GLEANINGS, and trading with you. By the way, you may not have heard of his sad death. He was returning from New Orleans, about three weeks ago; and in crossing the Ohio River at Evansville, Indiana, in passing from the transfer-boat to the tug-boat, he fell overboard, and not even his body has been found up to date. He was one of our best citizens, having many ennobling qualities. El Dara, Ill., April 2, 1885. T. C. BUNKER.

We are very much pained to receive the above news, friend B.; but I have given it here because a caution is needed to those who are not much accustomed to traveling. Do not incur risks. There is rarely a case where plenty of time is not afforded to get on or off from boats or trains. Wait until the proper time comes, and be careful how you step, or what you do. Many lives are lost because people get restless and uneasy in traveling. They get out on the platform, or get off at stations, simply for curiosity. Better keep your place, and move with the crowd, in an orderly and careful manner. I was not aware that people are often lost in the way you mention, so that not even the body can be recovered.

WOOD VS. TIN FOR SEPARATORS: ARE WIDE FRAMES TO BE LAID ON THE SHELF?

Before stating a few facts I wish to say I have great faith in A. I. Root. I believe he will publish any thing he thinks is for the interest of bee-keepers, even though his sales should be greatly lessened thereby. It does seem a pity that so many tons of tin are sold for separators, money wasted, when (fact No. 1) there are bee-men in this county who have raised comb honey for 10 or 15 years, keeping from 100 to 200 stands, who would not use tin for separators if it were furnished free of charge; they like wooden ones better. Another fact. Just now when the Heddon system is all the rage, and wide frames are to be laid on the shelf, it has been demonstrated in this county, by two years' experience, that a hive using wide frames will average double the honey to the hive, right through the apiary, that a hive will using the rack on top.

Bees have wintered all right where taken care of and fed. I have lost and doubled down to 125 from 160. This is the first time I have worried the editor of a bee-journal, and perhaps the last.

15—F. J. FARR, L5—160.

Buckner, Mo., April 8, 1885.

Friend F., you will never weary the editor by giving him plain facts from experience, like the above you have stated. Our experience with wooden separators, however, seems to be just the other way from what you state it; but perhaps ours were not made right. Although we have advertised wooden separators for some time, our customers seem to prefer tin to any thing else, and this year is no exception to the years that are past. I am inclined to think a good colony will usually store more honey in wide frames than with any arrangement we have yet had in the way of crates or cases. The extra trouble of handling wide frames, however, may more than make up the difference.

A SUGGESTION IN REGARD TO HAVING THE MOORE OR HEDDON CASES SO MADE THAT SEPARATORS MAY BE USED.

I would suggest an improvement in the Moore's crate, so that it can be used with separators. Instead of making the ends and partitions in one piece, have a piece an inch or $\frac{3}{4}$ wide, to which fasten the tin and a piece $\frac{1}{2}$ inch wide, even with the top to stiffen the rack, and hold sections square. A separator 2 $\frac{1}{4}$ inches wide can then be used between each row of sections. I have made some racks like the above, and think they will answer my purpose better than any thing I have seen.

In reading the article on wide-top brood-frames, by Alley, I think, the following idea came into my head, and I should like to have your opinion of it. Would not a strip of tin 1 $\frac{1}{2}$ inches wide, tacked on the top of the brood-frames, prevent brace-combs up to the rack, and at the same time leave each frame loose?

P. A. GARRETTSON, 28—35.

Hillsborough, N. J., Apr. 7, 1885.

Friend G., your suggestion is ingenious, and is to me a new thought. I presume you mean that the upper strips should be made movable, although you do not say so. It would be a little more work to make and to handle them; but the separators would go in nicely. There would be one trouble if sections were to be removed as fast as filled: The bees would get over into these spaces between the sections, and could not be got out without some care and trouble in replacing. In these spaces they would probably be imprisoned, and starve to death. The loss might not be great; but I should never want to close a hive, knowing that I had left a single bee in that predicament. Tacking thin pieces of wood temporarily to the top-bar of a brood-frame is an idea that was experimented on and reported in the *A. B. J.* as much as fifteen years ago. I believe it did not give very good satisfaction, though tin bars might succeed better; but I think it would be a good deal of machinery and bother.

FIVE SWARMS IN SUCCESSION FROM A SINGLE HIVE.

I have one hive of bees that have sent out five swarms since March 1st; the four last swarms came out in succession, one each day. James H. White, of this place, says that he has never heard of such a thing before, and that he doubts their having queens. What do you think of it? They seem to be working all right. The first swarms have made combs.

GEO. CLEVELAND.

Rockledge, Fla., March 20, 1885.

Friend C., my explanation of this matter would be, that the old queen was lost by some means, and a lot of young queens were raised. Instead of the first ones destroying the rest of the cells, a lot of them got loose at once, as sometimes happens; then came secession and dividing up. Do you not find that it is a week or two before any of these swarms have eggs in their combs?

CHAFF HIVES NOT BEHIND SIMPLICITY HIVES, AFTER ALL.

In your answer to my letter in *GLEANINGS* of April 1 you were surprised at loss of bees in chaff hives, while none were lost in Simplicity hives up to date. In justice to the chaff hive, I would like to add, that the bees in Simplicity hives all died in the

following severe weather of March. I found, upon examination, their stores were much the better—which accounts for their holding out longer. I have five swarms left in chaff hives.

LaGrange, O., Apr. 15, 1885. E. F. WILCOX, 35—5.

Friend W., I am not glad to hear that you lost the bees afterward, in Simplicity hives, but I felt pretty sure there was some reason for this apparent difference. From the way in which you speak of stores, we might infer that the trouble was not in the severity of the winter, but in the lack of stores. Now, suppose you had fed them up until sealed stores of sugar syrup were all around the cluster, as I have told you; namely, behind and before, on the right and on the left, and overhead and under foot; that is the way I like to see bees provisioned. When they are fixed that way, my experience has been that they get along a good deal better than where there is a good heavy comb off at one side, or several pounds of honey in the further corner.

REPORT FOR THIS LOCALITY.

One man had 11 colonies, and lost all; another 10, lost all but two; another 14, lost all but one; another 1, and had 5 left three weeks ago, but thought it rather doubtful, as they were so weak, about getting through at all; another man living right near here had 16, fall count; and some in chaff hives had, the first of this month, only two left, and those very weak and feeble.

Some time ago I spoke of having dragged out a queen from under a hive. I took it to be one, at least, and took it with a worker-bee to a very prominent bee-man of our county for examination, and he pronounced it a queen at first sight. It was shriveled up considerably, is what bothered me; so after writing to you it stayed so cold I thought it useless to think of getting a queen in time to save them, and the 24th day of March I drew the hive out of winter quarters for the purpose of distributing among the others, and, on taking out the second frame, I discovered young bees; and on the fourth frame, eggs and larvæ, of a fine hybrid queen, which gladly surprised me. Now, there is a mystery somewhere.

E. B. HAUGHEY.

Pearson, Fayette Co., O., April 13.

No mystery at all, friend P. The hive you mention had two queens, a young one and an old one. The old one died, and you had the young one left. When she was fertilized last fall she met a common drone, and therefore the brood will be hybrids.

APIS DORSATA; A SWARM CAPTURED AT LAST.

As a postscript to my last letter on *A. dorsata*, I have the pleasure to inform you that I have at last captured a swarm, and have it safely hived in an observatory hive. There are about half a bushel of bees, and are they not magnificent fellows? My hive is about 6 feet tall, and 3×3 wide and deep. The bees were secured on a very high tree, on which were 13 other swarms. The limb was cut off, and forms the top-bar for the brood, and hangs like a Simplicity frame in the hive. I have had a sheet of glass, 9×16 inches, put into the back of the hive, and a door made to shut all up, when one does not want to watch them. The brood-comb is about 14×16 in., and is solid with brood. I see no pollen or honey in the comb. There are young bees and

old. The old have the abdomen a bright yellow, with narrow black bands, while the young (?) are much darker in color. But I can not speak with much certainty, for I have not studied them long enough yet. They sting, but the sting is not much worse than that of the *A. Indica*—at least I judge so; in putting them into place, my assistant was stung four times, but it was not followed by swelling. The sting is much larger than the common bee, of course; and as one of my Karens said last night, "It makes a hole at once." Yet I judge that it is bearable.

Their wings are beautifully iridescent; and looking at them on their comb by night, with a strong light, they are most beautiful. This morning they are going out and in their hive, and looking all about their home. Will they stay and go to work or not? is the question; we shall see. I have saved some of the dead ones to send to you when they are dry; and as I learn more about them I hope to have something of interest and use to report.

One thing I notice. They are far less excitable than *A. Indica*. They move slowly, do not dash about their cage, and struggle for exit like that bee. They impress one, however, with an idea of "reserve power," if they have a mind to use it. I do not think they are quick on their combs to repair damage, but can not yet speak with definiteness. I wish this swarm were safe in your apiary. I also have a swarm of the "*melipona*" working well.

Toungoo, Burmah, Mar. 7, 1885. A. BUNKER.

MORE ABOUT THE WILLOW HERB.

For two years I have noticed my Italians working on the willow-herb, or purple fireweed. It is beginning to grow in profusion here, and I have several times been on the point of sending off a sample, for name; but your description of it, on page 48 of GLEANINGS, is too clear to leave room for doubt as to its identity. We live near the summit of the Allegheny Mountains, 1400 feet above sea-level, in the pine and hemlock regions; and as the timber is being cut very fast for logs and tanbark, the fire overruns the hills every year or two, and both species of fireweed grow abundantly, and both yield honey, as I am informed; but the purple is the only one on which I have noticed the bees working; and, by the way the bees "take" to it, and the length of time it is in bloom, it must rank next to white clover here as a honey-plant, and our honey is of excellent quality. It has the peculiarity of sending up a flower-stem, which begins to bloom at the base, and frequently the lower seed-pods are in "cotton" with matured seed, while the flowers at the top are just opening, which makes the honey-flow of long duration. I have kept bees but two years, so I suppose I belong to the A B C class. I got of comb honey, 400 lbs. ABEL GRESH, 7-26.

Weedville, Pa., Jan. 29, 1885.

CONCERNING DEAD OR TORPID BEES.

The other day I found a colony that had been breeding rapidly, and had exhausted their stores, and several cold stormy days had prevented me from supplying their need. They stood thick on three or four frames, all apparently defunct. Holding up a frame to look more closely I breathed on them, and saw a faint tremor of wings and legs. Near by was a queenless colony with a few workers and drones, small dark fellows whose heads I had pinched off a short time before. I got these orphans

on two combs, and put them between the dead ones. The queen fell on top of the frames, and the live bees rushed up astonished.

Take her up tenderly,
Lift her with care,
Fashioned so slenderly,
Young and so fair.

Well, they warmed her up and fed her, and resuscitated all her family—twice their number. Query—Will a queen that has been starved and chilled produce any thing but drones hereafter? I believe the authorities say she will produce only drones.

D. F. SAVAGE.

Casky, Ky., March 30, 1885.

Friend S., your queen will, without doubt, be just as good as she ever was. We have resuscitated a great many in the same predicament, and never found them drone-layers, although more severe freezing might perhaps have that effect.

CELLAR WINTERING.

I came out last spring with 15 swarms; lost 33; 8 of the 15 were good swarms; increased to 34; got about 20 lbs. surplus to the hive. Last year was a poor one up here. I fed a few swarms up on sugar; put them in the cellar the 20th of Nov.; my cellar I built last fall on purpose for bees, under my house. It is very dry, but still there seems to be something wrong with my bees. All through December, up to the 15th of January, they were noisy. They would crawl out and drop on the floor, and die. The ground was covered in front of the hives. When I put them in I raised them off the bottom-board one inch. The 15th of January I let them down on the bottom-board, and shoved the hive back, so there was an opening on the back. Since then they have been quiet, and but few bees dying. I examined them to-day, the 17th of February. There seem to be plenty of bees, and not a damp or moldy comb. The glass stands 36° in the coldest weather, and moderate weather 40°. Now, what was the trouble? Will some one tell me through GLEANINGS? I have been a bee-keeper for 30 years, and thought I knew as much as any man, but find I can learn something yet.

L. REED.

Orono, Mich., Feb. 17, 1885.

Friend R., I am inclined to think your bees were too warm when they were so noisy. I do not believe letting them down on the bottom-board, and pushing them back, made any material difference. When the weather became cold, your cellar probably got colder, and this was what made them quiet.

A SOURCE OF PLEASURE IF NOT OF PROFIT.

I am a shingle sawyer, in a mill in the north pine woods of Michigan. Four years ago I bought a swarm of bees in their natural home, a large pine-tree. The next year I had five swarms from them; but being inexperienced I have not yet derived much profit from them; still they have been to me a constant pleasure. Though being in a mill at work, I am very anxious to learn how to prevent natural swarming.

I began this year to take the *Apiculturist*, and sent you for a sample copy of GLEANINGS, thinking to try it for six months. Upon receipt of it I read the article entitled, "The Michigan State Convention; What I Saw and Learned," and decided at once to take it.

C. F. JOHNSON.

Deer Lake, Mich., Feb. 2, 1885.

ARTIFICIAL COMB HONEY.

The Philadelphia *Farm and Garden* calls their April No. their annual strawberry number, and a grand good number it is; but one of the best things in it is an editorial, hitting a blow at just what we have been writing on for two months past. See what you think of it:

Our vocabulary has no words strong enough to condemn in fit language such "scientific pleasantries" as the one which appeared lately in the *New York Mail and Express*, and has since been going the rounds through the American press. The article is given prominence by the flaring headlines: "Human Ingenuity to do away with the Work of the Bees," and describes an imaginary and utterly impossible method of manufacturing comb honey artificially, altogether without help of the bees. While American bee-keepers have been and are still working earnestly to find a market for their produce, while even now the purest extracted honey goes begging in our city markets on account of the glucose scare, the great city papers try to make all these efforts come to naught, and to make the consumer afraid of the most natural, most delicious, and most wholesome sweet, in the shape of comb honey.

This so-called scientific pleasantry is nothing but a willful and malicious lie, and one which strikes a fatal blow at the interests of the American bee-keeper. The great newspapers refuse to yield to the demands of interested parties for a proper correction. The damage seems to be well-nigh irreparable, for the agricultural press does not reach the honey-consumer in the cities, among whom a press so hostile to agricultural interests chiefly circulates.

Let us say, however, that both the inventor and publisher of such infernal lies deserve a good long term of free board and lodging in the penitentiary.

REPORTS DISCOURAGING.

SHALL HE GIVE UP?

MY subscription to GLEANINGS has run out, and so have my bees; and I am in doubt whether to have any thing more to do with either. A year ago I lost 30 colonies, but had 20 left; and although they were very weak I got about 700 lbs. comb honey, and increased to 30 colonies. I put them in the cellar with ten frames of honey to the hive. I filled the half-story cap with fine shavings, and tacked sack cloth over, and put on the hive with the oil cloth removed. I put 15 in a wing cellar, and 15 in a cellar under the wood-house, both shut off from the middle cellar. I did this because I thought I kept them too warm the winter before; but this winter has been so very cold that I presume the temperature in the wood-house cellar was down to 0 for six weeks at one time, and that under the wing not much above it. Well, the bees are all dead, and most of the honey left, and which is molded slightly in a few hives.

I think I shall not give up entirely, but get a swarm or two and try again on a small scale. I began with two swarms, which increased to fifty in three years, and I spent considerable on Italian queens, etc., but they are all gone now.

Stevens Point, Wis., Apr. 21, 1885.

GEO. H. PATCH.

Friend P., your bees were no doubt worse off in that cellar than they would have been outdoors, and this is one great reason why I have been so loth to advise wintering. The temperature of your cellar went down to zero, you say. Well, the tendency of the cellar then was to keep the bees at zero when they would have been warmed up a great many times if outside. The same way we

often find frost even now under heavy mulch. During the severe weather it froze down to a great depth, and the mulch, or protection, has had the effect of keeping or prolonging the excessively low temperature. Chaff hives, you will notice, may let the temperature go down to zero, or even below it; but they also permit it to rise, when the surrounding air rises, in a comparatively short space of time.

LOSS ON ACCOUNT OF HONEY-DEW.

The loss in bees through this section the past winter is the heaviest that has ever been known—fully 95 per cent. Cause, no good honey last season after June, hence the region of the brood-chamber was supplied late in the season with an unusual amount of pollen and a small supply of bug-juice. Bees that were fed in the fall on sugar or good honey have wintered well.

R. B. ROBBINS.

Bloomdale, Wood Co., Ohio, Apr. 1, 1885.

ONLY 2 LEFT OUT OF 53, CAREFULLY PUT UP FOR WINTER.

Last season I increased to 60 colonies; but as we had almost a total failure of honey I had to double back to 53 in the fall. I fed 15 colonies 150 lbs. granulated-sugar syrup. I put a Heddon case on the top of each hive, filled with dry forest-leaves, and left them on the summer stands. Now for the result:

Out of the 53 thus prepared I have just *two* weak colonies left! Surely I am ready to go into Blasted Hopes. No, *don't* put me there, for I am going to "try again." I have the hives, combs, etc., and I propose to get some bees by the pound, and stock up again. I find sealed brood in nearly all the hives, the eggs evidently laid during a warm day or two we had about the 7th or 8th of Jan. This divided the cluster, and caused the bees to spread over the patches of brood, and thus they perished with the long protracted cold that followed; but, what induced the queen to lay so early in the winter? Was it because the honey of last season was miserably poor stuff, gathered from grapes, some rotten apples, and unusually mixed with pollen? It was so pollenized as to be, much of it, absolutely bitter; much of it was watery and sour. Most of my colonies had diarrhoea badly; some had 25 to 30 lbs. of honey left.

At the meeting of our N. Kansas Bee-keepers' Association, held April 3, the reports were gloomy enough, one or two exceptions, and those were in favor of the *cellar*. I think that the losses in this region will not fall any short of 90 per cent. Some have lost all; most have only one or two colonies left.

J. W. MARGRAVE.

Hiawatha, Kansas, April 17, 1884.

ONLY 21 LEFT OUT OF 80.

I think that fully three-fourths of the bees in this county are dead. I had 80 stands last fall; now have 21 left, many of those with only a handful of bees in a hive. Many I hear of have lost every swarm. Ellwood Spencer, a neighbor, has 15 left out of 80 last fall. I wintered 46 of mine on their summer stands in Langstroth and Simplicity hives; 9 out of the 46 are yet alive; 34 I had in a cave, and 15 of those are alive. Most of those that died in the cave starved to death, while those on their summer stands left plenty of honey.

S. L. SHERMAN.

Oskaloosa, Iowa, April 7, 1885.

REPORTS ENCOURAGING.

WINTERING IN A SIMPLICITY HIVE WITH NOTHING BUT A MAT OVER THE FRAMES.

THE past winter reminds me of the winter of 1880. I hear of heavy losses of bees all around in my vicinity. I have not lost any except one four-framed nucleus. The greater portion of my 54 colonies are in excellent condition—just booming with bees. I had one colony that wintered in a Simplicity hive with nothing over the frames but one of your basswood mats and the hive-cover. I was afraid to examine them, for I was almost sure that I should find them dead. You may imagine my agreeable surprise to find them in good condition. The queen is a large, prolific, full-blooded Italian; and her workers, large, hardy, and good honey-gatherers. They were on 9 "slabs" of white-clover honey that they stored away themselves. This is pretty good evidence, I think, that bees will not freeze, but still I think it pays to give the little fellows proper protection; and after five years' experience with Root chaff hives I consider them the best hive for both winter and summer use. I always find bees all right in chaff hives; combs dry, and hive nice and clean.

J. P. MOORE, 54-55.

Morgan, Ky., Apr. 14, 1885.

Friend M., my opinion is that your bees in the Simplicity hive were so strong and healthy, and so full of good wholesome stores, that they came out all right *in spite* of bad protection.

A GOOD REPORT FROM OREGON.

Apr. 5 we had one swarm come off, and a big one too; yesterday two more came off, and all our stands are very strong, with lots of new honey. Think of it, over 600 miles north of Chicago, and surplus honey in March! "Busy bees" haven't lost an hour on account of weather since March 1st. We have some very fine apple-bloom honey, sections complete, and now white clover is coming out fine; look out for astonishing reports. No feeding has been done, none needed. Of course this is not usual, as we have generally to complain of considerable moisture in March.

CHAS. LEE.

Portland, Oregon, April 8, 1885.

MY RECORD FOR 1884, FROM 11 TO 40, AND 1620 LBS. OF HONEY.

Spring, 14 colonies; honey, comb, 450 lbs.; extracted, 1170 lbs.; fall, 40 colonies, five nuclei, 1885. Spring, 40 colonies, four nuclei. How does that look? No Blasted Hopes there. E. B. CRANE.

New Canaan, Conn., Apr. 13, 1885.

275½ LBS. OF HONEY FROM 22 STOCKS.

The year 1884 was an unusually good season with me for honey; from 22 stocks, spring count, I took 2450 lbs. in comb honey, and about 300 of extracted, mostly sold, averaging about 16½c. My bees are all in tiptop condition to date, notwithstanding they have had access to plenty of pollen. This is the fourth season I have packed them on summer stands without regard to pollen (but a good supply of early-made honey), and have never lost a stock, or had any signs of dysentery in my yard. I get most of my swarms in May; pollen is no terror with me, providing I have the other requisite.

C. L. BOSTWICK.

Sandy Hook, Conn., March 28, 1885.

ONLY ONE LOST OUT OF 121 IN WINTERING.

We take pleasure in sending in our report this spring. Cellared 120 colonies, Nov. 17, 1884; finished setting them out, Apr. 15, 1885. One dead in cellar, one swarmed out since setting them out (queenless); perhaps there are six to ten that will have to be helped some, as they are rather weak; the rest are in nice shape, except they may need feeding some on account of no fall run of honey last season.

D. E. L'HOMMEDIEU & BRO., 905-120-5000, Colo., Ia., April 19, 1885.

P. S.—5000 stands for the surplus taken in 1884.

ONLY 2 LOST OUT OF 80.

Our bees have wintered well; lost only 2 out of 80. Bees have been gathering pollen for the past two weeks, and are building up very fast. I think we have done very well, considering the losses of the older bee-keepers.

WM. M. ROSS.

Lebanon, Ills., Apr. 10, 1885.

A GOOD REPORT FROM CAVE WINTERING.

I put 55 stands of bees in a cave the 1st of December, and took them out the 1st of April. Two were weak when put in, and should have been united when put up. They went up. The mice destroyed the rest; all came out right. Experience has taught me that plenty of ventilation is the one thing necessary to successful wintering in caves. I have a 4-inch chimney in the roof of my cave, and last fall I put a 4×4-inch tube, 16 feet long, below the freezing-point down in the ground, and brought it into the cave at the bottom at one corner, and during the very cold weather I put an oil-stove in the cave and kept the temperature at from 40 to 45°. I never had bees winter better than last winter. The cave is in a sandbank, nice and dry.

JAS. H. BROWN.

Cherokee, Iowa, April 7, 1885.

ONLY 3 LOST OUT OF 130.

On the 20th of Nov., 1884, I put 130 colonies into my cellar. On the 5th of Apr., 1885, I carried out 127 live colonies. At the present date there are 10 colonies that are weak, the rest very good. I packed 9 colonies in chaff, on summer stands, 5 of which are dead. The rest are fair colonies. Yesterday it was 25° in the shade at 7 A.M., and froze all day. To day we have a furious snowstorm, with no sign of improvement. Not very encouraging weather for bee-keepers.

W. ADDENBROOKE.

North Prairie, Wis., Apr. 14, 1885.

THE SYRIANS AHEAD.

My report for 1884 is small. I lost all my black colonies but one, and sold that. One colony of Syrians increased to 5, and gave 30 lbs. of honey. I should have tried for more honey and less increase, if I had been at home.

E. L. TARELL.

Presque Isle, Me., March, 1885.

FROM ONE TO FIVE, AND 50 LBS. OF HONEY.

I bought one colony in Nov., 1883; increased to 5; got 50 lbs. of comb honey. They are all alive at this date. I have them packed in chaff. This winter has almost cleared this neighborhood of bees.

Howells, Mich., Apr., 1885. DILLAN GEORGE.

LESS THAN 5 PER CENT LOST IN AN APIARY OF 175 COLONIES.

Bees have wintered splendidly; less than 5 per cent out of about 175 colonies; about one-third in chaff hives, the rest in single-walled hives; all wintered out of doors. I can see but little or no difference in the results of the different hives; all

had chaff cushions, but none had chaff-cushion division-boards. Those that died, died of starvation; but the prospects are not very promising for a good honey yield for the coming season, as the clover is badly killed out in many places.

Centerville, O.

G. W. LAWSON.

I would not be in haste to borrow trouble. friend L., for the clover sometimes catches up wonderfully, under the influence of favorable weather.

FROM 4 TO 11, AND 145 LBS. OF HONEY, ETC.

I began the spring of 1884 with 4 colonies; increased by natural swarming to 11, and took 145 lbs. comb honey. Now a question: Do bees raise bees all winter, even when it is freezing cold? On the 26th of February I found 6 fresh young white-winged bees in front of one hive, that being about the second day that was warm enough for them to fly for about a month. They carry pollen into every hive now when it is warm enough. J. S. DANIEL.

Siloam Springs, Ark., March 8, 1885.

Bees do raise brood every month in the year, even away up here amid our frosts and snows, friend D.; that is, they do occasionally. Most colonies will, however, have but little brood during December; but in January and February, almost all strong colonies contain more or less.

ONLY ONE DEAD OUT OF 73.

Out of 73 colonies left on summer stands, packed with straw and chaff, one has died. The rest seem to be in pretty fair condition, as they seem to want to rob one another pretty lively, while all defend themselves well. The neighbors report some all dead, and some about three-fourths, and others one-half dead, while some think the survivors will perish on account of not having enough honey to build up on. While the cold weather still stays with us, having a snow this morning two inches deep, not much prospect for a very early spring.

Lima, Ill., March 21, 1885. J. A. THORNTON.

FROM 4 TO 13, AND 300 LBS. OF HONEY.

Here is my report for 1884: Spring count, 4 hives; increased to 13 by natural swarming, and got 300 lbs. comb honey. I took GLEANINGS last year, and have the A B C book, and I like them very much.

F. B. STEPHENSON.

Deep Water, W. Va., Feb. 17, 1885.

FROM 6 TO 10, AND 120 LBS. OF HONEY.

We commenced last spring with six stands of bees; increased to ten, which are all alive at present, and got 120 lbs. of comb honey, surplus. The honey season was cut short by the extreme drought.

F. C. THOMAS.

Spring Valley, Ohio, March 17, 1885.

ONLY ONE LOST OUT OF 24.

In the last issue of GLEANINGS I notice many discouraging reports, especially to beginners; but I shall take fresh courage, and go ahead. I started in last spring with 14 colonies in hives of my own make, movable frames, no name for them. I increased by natural swarming to 30; united to 24; came out this spring with 23, some dead bees in each colony. Through the coldest weather in January and February I kept them covered with snow, head and ears—no other protection, except quilts over the frames. I will try to do better next winter.

Please tell me how to save comb from the moth during summer, as I can get all the comb I want

from my neighbors who have lost their bees. I can buy all the bees I want for \$1.00 to \$1.50 per colony, in box hives.

E. FARABEE.

Tina, Carroll Co., Mo., Apr., 1885.

Friend F., shut your combs up in a tight box or tight room, where the moth can not get at them, and there will not be any trouble in keeping them over summer. See Bee Moth in the A B C book.

A GOOD REPORT FROM FRIEND PEIRCE.

Nov., 1884, 46 colonies; Apr. 20, 1885, 42, and better filled with bees than any previous spring—chaff hives, sack of dry soft shavings over the frames, front entrance of the hives all open. The 4 dead colonies were full of bees, but starved. I am ashamed to write it.

J. H. PEIRCE.

Dayton, Ohio, April 20, 1885.

ONLY ONE LOST OUT OF 33; SAVED BY NEGLECT.

Contrary to expectation, my bees have wintered well, having lost but one out of 33 last fall, and that one was queenless. My bees were not prepared at all for winter, on account of my absence from home when they should have been cared for, and my inability from rheumatism and heart disease after getting home. They were all just as left, about the first of July. Some had wide frames with section boxes in the upper story (chaff hive) and some were full of L. frames above, with nothing but roof of hive above the frames, and others were partly full above, and some with cushions or honey-board above brood-nest, and all did equally well, as far as I can see. Some had the upper story full of sealed honey, and some not very much. It was very dry last fall, and I expected the bees around here would die of old age. Many did; but mine were saved by neglect.

T. F. WILSON.

Milan, Ind., April 12, 1885.

Friend W., it does seem as if your bees lived in spite of their want of care; but I guess the truth is, they had an abundance of good wholesome stores; and when this is the case they will stand almost any kind of ventilation.

MRS. LUCINDA HARRISON'S REPORT.

We commenced to carry our bees from the cellar April 1, and they are now all on their summer stands. I've not examined them yet, but, judging from their flight, they are generally in good condition. It is cool to-day, as there was a hard freeze last night, which formed thick ice. Bees carried in pollen on the 4th and 5th of April, for the first time this season.

BEES UNITING IN THE CELLAR OR BEE-HOUSES.

Do bees ever unite in the cellar? Our bees had on Hill's device, covered with a muslin sheet and comforter, and piled one upon another with intervening sticks. A few hives had no bees; and in every instance the hive beneath was running over with bees, appearing as if they had moved into one hive.

Mrs. L. HARRISON.

Peoria, Ill., April 8, 1885.

Yes, my friend, they will unite very often when the hives are too close together, and a broad entrance permits them to pass to and fro. You will have all your bees left, but are usually minus a queen. If you examine these overpopulous colonies as soon as taken out, however, you will oftentimes find both queens alive; and by promptly dividing a colony you will be all right again.

TERRY'S BUSHEL BOXES.

BOXES VS. BASKETS.

FOR a long time I have been thinking that we ought to have something more accurate than a bushel basket—more substantial, and less expensive. Baskets do not fit up tight together in a wagon; they won't bear piling one on top of the other, and they cost more than a good stout box. When I read the proof of friend Terry's potato-book I was greatly surprised to think he had been following my own notions so fully. The following is the chapter in regard to these boxes:

THE USE OF BUSHEL BOXES.

For several years I have been using bushel boxes for marketing early potatoes, while the skins slip, and for handling the crop in the field all through the season. This is one of the ways in which the potato-specialist can get ahead of the small raiser. I think we handle our crop for less than half of what it used to cost us before we got these boxes made.

Our boxes are 13 inches by 16, and 13 deep, all inside measures. They were made a little deeper, to allow for shrinkage. The sides and bottoms are made of $\frac{1}{2}$ stuff, and the ends of $\frac{3}{4}$. Hand-holes are cut in the ends as shown in the cut.

TERRY'S BUSHEL BOX.

The upper corners are bound with galvanized hoop iron to make them strong. The price paid for them was from \$25.00 to \$30.00 a hundred at a box-factory. The wood used is mostly whitewood. Some light wood should be used, of course, so as to make them as light as possible. They need not weigh more than six or seven pounds. Early in the season, while the skins slip, our potatoes are dug and laid (not thrown) into these boxes, and the boxes are covered as fast as filled. They are then safe from sun and rain till wanted for market. The covers are simple pieces of boards cut about 15 by 18 inches. Dig one day and taken to market the next, and set off in the boxes at the grocer's, and then set by him into his delivery wagon and taken to his customers, the consumer gets them just as nice and fresh as though he raised them himself. I recollect once leaving 30 boxes at a grocer's while I went on with the rest of my load to another place. When I came back he had delivered every bushel to his customers, who had orders in for them. They were dug in the afternoon, immediately covered, and by 11 o'clock the next day they were in the consumer's cellar, without any handling or bruising, and I will warrant they gave satisfaction. There is plenty of demand for nice things at paying prices, while ordinary goods are dull at low prices. Some buyers, I know, or shippers, do not seem to appreciate nice potatoes, carefully handled; but our best city grocers are generally on the lookout for the best, and are willing to pay for it. Of course, these boxes filled with potatoes should be carried on a spring wagon, and covered by canvas from sun and rain. The sized box spoken of is just right to set in an ordinary three-foot-wide wagon-box, as two boxes endwise just fill across the wagon-box. The box on my spring wagon is a little over 12 feet long, so 20 boxes can be set in the bottom, and two deep makes 40, our usual load for two horses. But they can be set three or four deep, if desired. The boxes hold a bushel level full, so they can be set one top of the other. Do not round them up, or you will cheat yourself. They hold a full bushel when a straight-edge drawn across the top just touches the potatoes. With plenty of these boxes, my men can dig right along while I am going to market, and I can load up any time in fifteen minutes. There is some dead weight to carry, but it pays twice over. The potatoes are in the nicest possible shape, and your customers will soon find it out, and there is no chance for quibbling about measure. There is just a bushel in a box every time, while baskets vary in size, and can easily be

heaped up too much or too little, thus giving a chance for unpleasant words between buyer and seller. Later in the season, after the potatoes are ripe, and there is no longer any need of handling them so carefully, I drive through the field, and two men will empty 50 or 60 boxes into my wagon in a very few minutes, and the boxes are left ready to be filled again. When picking up we do not need to have a team and wagon in the field; they can be going to market, or at other work. When there is a good crop, a box can be filled almost without moving it; thus all unnecessary lifting and carrying are avoided. Last fall we wished to dig one six-acre piece and pile them close to one edge of the field, so we could plow the land. The boxes were scattered through the field, and, when filled, were set into the wagon and drawn to the place where we wished to pile them, and emptied out, 50 bushels in a pile. A gentleman from New London was here, and rode with me on the seat while two men handled the boxes. He was much surprised to see how short work we made of clearing off an acre. There is a great difference in the amount of labor as compared with the ordinary method of handling. Really, I do not mind the raising and handling of 24 acres of potatoes now, with every possible device that Yankee ingenuity can invent to save work, as much as I used to the raising of six acres a few years ago. When we want to put the crop into the cellar we manage the same way as when piling, except that the boxes are emptied on to a shoot in the cellar window. When a car is to be loaded right from the field, these boxes come handy also. We can get a carload dug beforehand, and have them all in the boxes and wagons, so the car can be loaded in a day. We do not have to stop to pick them up out of piles, and thus a very unpleasant as well as slow job is avoided.

At the end of the season, when the boxes are filled for the last time, they may be carried down cellar and stored away full of potatoes, or apples may be put in them. There is no nicer way of marketing winter apples than in these bushel boxes. Again, in the spring they are just the thing to have the seed around in when cutting, and to carry it to the field in. A boy can wheel the boxes out to the planter as fast as the cutters fill them. A man who worked for me before and after these boxes came around often used to say, "How did we ever get along without them, they are so handy?" In the field, if covers are scarce the boxes may be carried together and set up three or four deep, and then one cover will answer for all. These covers are almost as important as the boxes. We used to carry the boxes together into piles or heaps, and then cover them with a canvas or rubber blanket, and it was quite unhandy. When I was riding to market one day I got to studying over the matter, and it occurred to me that a simple board cover for each box was just what was wanted. Strange that so simple a thing hadn't been thought of before. I went to a mill and had 150 sawed, and took them home with me, and found them to be just the thing. In catching weather, if the potatoes are picked up as fast as dug, and covered, they are all right and ready to load into the wagon any time after it stops raining. One is as independent as possible of the weather.

You will notice that friend Terry says they cost him from \$25.00 to \$30.00 per 100. Well, we have discovered that, by the use of our machinery, we can make nice strong ones, made of light strong basswood, bound clear around the top and clear around the ends with galvanized iron, at the following prices: 25 cts. each; \$2.25 for 10, or \$20.00 per 100. Stuff in the flat, including nails and galvanized iron, \$1.75 for 10, or \$16.50 per 100.

The boxes are extremely handy for a great variety of purposes, aside from apples, potatoes, etc. If you want to pick up stones in the field, they are not strained or pulled out of shape as baskets are; and whatever you put into them is accurately measured. If you want a hen's-nest, I do not know how you can do much better than to take one of these potato-boxes; and if any one should ever want to hive his bees in a box hive,

here you have it of the old orthodox dimensions, and a nice entrance at both front and rear. Perhaps I might add, that, in the way we make them, some ventilation is allowed. The end boards are exactly 13 inches square. Two, exactly alike, are required for a box. Well, the sides and bottom are all made of pieces of board exactly alike—six being required to make the box, each one of these pieces being $17\frac{1}{2}$ inches long and $6\frac{1}{2}$ inches wide. In nailing, first nail a piece on each side, flush with the top edge of the box. Now put on the bottom, the edges being flush with the end-boards. Last of all, put on the two remaining pieces, nailing them into the bottom boards as well as into the ends. This leaves a crack at the middle of each side; and, if the boards ever shrink a little, a smaller one, in the center of the bottom.

If you want to try a potato-box, to see how handy they are to have around, just order one for a packing-box when you are getting some goods. We will send a sample, filled with goods, for only 15 cts., for it saves us the price of a box to put your goods into.

HAMBAGS AND SWINDLES

PERTAINING TO BEE CULTURE.

FRIEND ROOT:—I have got into considerable trouble from the party whose circular I inclose, as he claims I am infringing on his patent in using the oil or enamel cloth that I got from you. He claims that he has a patent on all cloth covers, every thing except boards, and warns me that I shall be prosecuted in the U. S. court. He has sold the right to use his hives in this county, for \$200, to a party in Rockdale. Please instruct me what to do. I am not able to stand a suit; it would ruin me, yet I have my forty stands of bees covered with such sheets, and have sold 70 hives, all with the same sort of sheets, so I am in for it.

WM. WASON.

Rockdale, Milam Co., Texas, April 18, 1885.

Friend W., tell the "Common-sense" folks to commence suit on me for using enamel sheets, if they like. I am, perhaps, the largest infringer, and have probably been using the enamel sheets more years than almost anybody else—certainly long before their patent dates. This is simply a rehash of Mitchell's absurd claims. The circular you send us is the usual one that is sent out with the Common-sense (?) hive. Some may urge that good men's names are appended to their testimonials. Very likely; but these good men have got into company most decidedly bad. No such a patent would be possible or rational. You can cover your bee-hives, or any other farm implements, with cloth, paper, or oil cloth, or any thing you choose, and there can be no patent on it. There is no danger of a suit at all. They are simply trying to blackmail you, friend Wason.

It seems that Prof. Cook does not hesitate to declare publicly where Mrs. Cotton and her hive belong. Surely she can not claim that Prof. Cook is interested in a bee-journal or a hive-manufactory. We copy the following from the *Rural New-Yorker* of Apr. 25:

Y. M. L., Panama, N. Y.—What about Mrs. Lizzie E. Cotton and her wonderful "Controllable" bee-hive? How many dollars' worth of honey will a hive of pure Italian bees make in a season, and how much is a hive of such bees worth?

ANSWERED BY PROF. A. J. COOK.

Mrs. Lizzie E. Cotton has been exposed as a fraud in the *Rural New-Yorker* and leading bee-journals for years. She says her hive and system will surely bring \$20 per colony each year. Such a statement is absurd. The season may be so poor that no honey will be gathered. Even the bee-keepers of Maine, in her own State, pronounce Mrs. Cotton to be a cheat. Her hive and system would not be accepted as a gift by the first bee-keepers of the country. A good colony of Italian bees will, in average seasons, give one swarm, and gather 50 pounds of fine comb honey. Our best bee-men sell good strong colonies, in our best hives—such hives are now unpatented—for \$10. Mrs. Cotton charges double this amount, and many of her patrons complain that what she sends is really worthless.

CONVENTION NOTICES.

The Mahoning Valley Bee-Keepers' Association will hold its next meeting at Newton Falls, Ohio, on Thursday, May 28, 1885. E. W. TURNER, Sec.

The bee-keepers of Western Mich. will hold their spring meeting at Fremont, Mich., May 5, 1885. All are invited to attend. F. S. COVEY, Sec. Coopersville, Mich., April 14, 1885.

The Central Michigan Bee-Keepers' Association holds its spring convention at Lansing, in the State Capitol Building, on Tuesday, May 12, 1885, at 9 A. M. E. N. WOOD, Sec.

No. Lansing, Mich., April 20, 1885.

The next meeting of the Central California Bee-Keepers' Association will take place in the park at Hanford, Tulare Co., in picnic style, at 10 A. M., on the first Wednesday in June. All family folks will bring their baskets; and bee-men generally are invited. GEO. HOBLER, Sec.

Hanford, Tulare Co., Cal., April 11, 1885.

The Northern Ohio Bee-Keepers' Association will hold their annual meeting in the Council Chamber, at Norwalk, Ohio, Saturday, May 9.

Several subjects of immediate practical value will be discussed. Officers will be elected for the ensuing year.

No one engaged in the production of honey can afford to be absent. H. R. BOARDMAN, Sec.

East Townsend, Ohio, April 15, 1885.

PENNSYLVANIA KEYSTONE BEE-KEEPERS' ASSOCIATION.

The next annual meeting of the above association is to be held in the court-house, in the city of Scranton, Pa., at 10 o'clock A. M., and at 1:30 P. M. on the second Tuesday of May, the 12th, 1885.

At the morning session, the annual election of officers will take place. While the association is but just commencing its third year, we feel to congratulate ourselves in having a working membership of fifty and upward; yet there remains much to be accomplished, and we trust that all who keep bees, whether for pleasure or profit, will make it their duty to attend this meeting, and bring their friends. Business of great value will be brought before the meeting. The question-drawer will be opened, and questions answered. Let everybody send a question. All are most cordially invited.

ARTHUR A. DAVIS, Sec.

Clark's Green, Pa., April 17, 1885.

CIRCULARS RECEIVED.

M. C. Kerns, Pomeroy, O., sends an 8-page circular of hives, section boxes, etc.

H. A. Goodrich, Massie, Texas, sends an 8-page circular of supplies generally.

O. H. Townsend, Alamo, Mich., sends us a one-page circular of bees and queens.

D. S. Hall, South Carol., sends a small 8-page circular; specialties, hives and fixtures.

J. C. Misher, Ligonier, Ind., sends us a one-page circular; specialties, bees, nuclei, and queens.

F. D. Wellcome, Poland, Me., sends us an 18-page circular, large pages; bee supplies generally, and small fruits.

Geo. T. Hammond, West Sweden, N. Y., sends a 2-page circular; hives, sections, etc.; specialty, paper boxes for retailing honey.

W. B. Coggeshall, Summit, N. J., sends a 6-page circular, specialties, bees by the pound, and nucleus colonies. Printed at this office.

S. P. Hodgson, Horning's Mills, Ont., Canada, sends a 20-page circular of hives and supplies generally; specialty, tinware for the apiary.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,

EDITOR AND PUBLISHER.

MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, MAY 1, 1885.

Finally, my brethren, be strong in the Lord, and in the power of his might. —Eph. 6:10.

NOTICE the decline in fdm., in another column.

ALSIKE CLOVER.

As we have still in stock a large amount of fine seed, we will, for the rest of the season, fill orders at \$9.00 a bushel; \$4.75 per half bushel, or \$2.50 a peck.

IMPORTED QUEENS.

Our apiarist reports 84 fine imported queens in our hives, wintered over. We don't think any of the brethren will be troubled by delays on imported queens this season.

MAILING QUEENS WITHOUT FOOD.

MISS NELLIE ADAMS, of Sorrento, Fla., mailed us a queen Apr. 23, and forgot to put any candy in the cage. It reached our office on the 23d; bees all dead, but the queen was alive, and when supplied with honey she seemed all right. Now, we would not advise mailing queens without any food; still, it is interesting to know how long they may survive. The weather has been warm and damp, which perhaps favored them somewhat.

INDICATING THE PART OF THE STATE IN WHICH YOU LIVE.

With the permission of the A. B. J. we will copy the excellent plan they have adopted for letting each subscriber tell what portion of the State he lives in. It is virtually the plan adopted by the Postal Guide. It will be understood with the following explanation; thus, ♂ indicates that the friend who uses it resides in the north-east portion of the State; ♀ indicates a southern portion, etc.

CONVERTING A HALF-STORY SIMPLICITY INTO A HONEY-CRATE.

WILL ELLIS, St. Davids, Ontario, near Niagara Falls, sends us a Simplicity half-story, arranged for holding sections on the Heddon or Moore plan, which still admits of using separators. It is essentially the same as the plan mentioned on page 314. It is quite ingeniously arranged, and fills the bill nicely, only it leaves those spaces for imprisoning bees. Trifling as it may seem, I should say that this of itself would be a fatal objection.

WIRE NETTING FOR POULTRY FENCES.

SINCE our last, an enormous trade has sprung up in wire netting for poultry inclosures. The factory

n New York became unable to fill our orders, then we induced a factory in Cleveland to take it up, until they got behind badly, then we struck a factory in Chicago, that bids fair to keep us going. A quantity sufficient to prevent any further delay has just been unloaded from the train. When we advertised to furnish it, we thought we had enough on hand to accommodate all the brethren; but, of course, we did not know there were so many who wanted just exactly the same thing. We shall keep in stock only the four-foot width, and in our own yards this seems to be high enough for almost any purpose (especially if a board one foot wide is put along the bottom) but we can furnish to order any width from two to six feet. If you want us to cut rolls, the price will be $\frac{1}{2}$ c. a foot extra. On two or more rolls, we can now give 5 per cent discount; on ten or more rolls, a discount of 10 per cent. As the above prices are very close indeed, they can be given only when cash comes with order. This wire netting can be used in a hundred different ways, for protecting any thing. As it is galvanized wire, the weather has no effect on it whatever.

THE PRAIRIE FARMER AND THE AMERICAN AGRICULTURIST.

It is amazing to look on and see how two good respectable journals—journals full of years of usefulness—can be so led astray by Satan as to come out in public and quarrel—yes, quarrel worse than a couple of juveniles might be expected to quarrel over some of their playthings. For the sake of decency, if nothing more, dear friends, do stop right where you are, and drop the whole matter. Fill your pages with something of value to your readers, as you have been wont to do. And do not any more, for the sake of the example you set, and for Christ's sake, put another word in print—no, not even in a circular, in regard to these personal differences. Perhaps the feeble voice of GLEANINGS may not count for much, but it may be worth something by way of suggestion. There is a little scrap from good old doctor Watts, that I have thought many times would apply to newspaper editors as well as to quarrelsome children. It seems to me it used to run something like this:

Let dogs delight to bark and bite,
Let fiends their madness prove;
Let brutes and mongrel swind and fight,
For God hath made them so.
But children, you should never let
Your angry passions rise;
Your little hands were never made
To tear each other's eyes.

If anybody else can fix the above better, let him do it.

FERTILIZING QUEENS WHILE IN THE CELL, BY MEANS OF DRONELARVÆ.

At New Orleans this subject was brought up, and some facts were brought forward derogatory to the character of those who claim to have succeeded by this process. Some of the friends may remember the originator of the process was a Mr. B. F. Lee, of South Oxford, N. Y., as given on page 296, 1884. We have written to the postmaster of South Oxford, but, to our great surprise and astonishment, he says he knows no such individual as B. F. Lee. Two of our subscribers at the above post-office reply in the same way. Now, unless Mr. B. F. Lee can come forward and explain matters, it seems to me he bids fair to prove an excellent candidate for the Humbug and Swindle department. I regret now that I did not ascertain more in regard to his standing, before I published his letter. The whole thing seems to be the old story of fertiliz-

ing queens in confinement, over again. In justice to Mr. John M. Price, of Tampa, Fla., who has given us the results of several of his experiments in this matter, I would say that we have known him for years, and know him to be a gentleman. Furthermore, his postmaster replies promptly that he is a gentleman of good standing and reliability. I feel sure that friend Price has been honest in the matter, but I fear he has been mistaken in some of the conclusions he has drawn from the results of his experiments. Now, then, can any one tell us about Mr. B. F. Lee? and can any explanation be given as to why any man should fabricate a letter having such a semblance to the truth as the one mentioned above?

A B C BOOK OF POTATO CULTURE.

The above little book, published by us and compiled by T. B. Terry, of Hudson, O., is now finished. Price 35 cts.; 3 cts. extra if sent by mail. Mr. Terry is well known throughout the State of Ohio by his talks at our farmers' institutes. He is also pretty well known throughout the United States as one of the foremost writers on agriculture, being a regular correspondent of the *Ohio Farmer and Country Gentleman*. Mr. Terry is not only a successful farmer, but he has done more, perhaps, than any other one man in the State of Ohio to raise farming from drudgery to a pleasant pastime. While the little book was written principally for the purpose of telling farmers how to raise a better crop of potatoes, it also touches largely on the great labor question of the day. It tells, in a plain, practical manner, how far brain-work may be made to take the part of hard muscular labor in all farming operations. It discusses intelligently, too, the matter of using modern machinery on the farm. Mr. Terry is a plain, practical man; and while he recommends the use of such machinery for agricultural purposes as has been, by long use, fully approved, he objects, in most emphatic terms, to investing money in new-fangled fertilizers in place of making use of the means to be found on every farm, for producing home-made manures; and he also objects to buying potatoes, or other kinds of seeds, at fabulous prices, when the probabilities are that we have already just as good in every-day use, if we make them do their best.

The book not only makes potato-growing a science, but it reduces it to a system, to be followed through half a dozen years. And, best of all, Mr. Terry works out his system and his theory, and makes it pay, too, as all his neighbors will tell you; and, in fact, you can catch him at it almost any day in the year; for by his method, farmers have no idle days, winter or summer, rain or shine. Neither is Mr. Terry a man who believes in no amusement; for after you have had his little book in your house, your boys may be more anxious to go into Terry's method of farming than they are to patronize skating-rinks.

The book ought to interest every one interested in the great problem of something to do, even if he be not a farmer. My friend, if, after you have read Mr. Terry's little book on potatoes, you decide it is not worth the 35 cents we ask for it, if you will slip it back in its envelope, and return it to us unsoiled, we will return you your money, paying all expenses, and no unpleasant feelings either.

WE have to-day, Apr. 30, 6462 subscribers a gain of 228 over last month.

KIND WORDS FROM OUR CUSTOMERS.

GLEANINGS AS AN ADVERTISING MEDIUM.

Please add that I have sold all the bees I have to spare by advertising in GLEANINGS, as I have become tired of answering letters. J. B. MURRAY, Ada, Ohio, April 1, 1885.

[The advertisement friend M. refers to was given only one insertion on page 218.]

THE A B C OF POTATO CULTURE.

[The following comes from the Ohio Agricultural Experiment Station, and we value it all the more because it gives our book a little criticism as well as kind commendation. Perhaps our people of the Ohio State University are as well prepared to judge of the merits of such a work as anybody anywhere.]

A. I. Root:—I have looked the A B C of Potato Culture through quite carefully, and am much pleased with it. It will pay any one who cultivates the soil, to read the book, whether he grows potatoes or not, for there are many things in it to set one to thinking; but to potato-growers it is invaluable. Mr. Terry's success gives force and weight to his opinions, even on matters where there is a chance for controversy. One feels more like trying the methods advised, because of the enthusiasm the book inspires, than controverting the opinions expressed. The facts stated are just about as near the truth as it is possible to get at present. If there is any criticism to be offered, it is in the style of the book, which is spicy, but not quite systematic and concise enough. In other words, the matter is better suited to the newspaper style than to the book form; but the truth is there all the same.

Very respectfully, W. J. GREEN, Columbus, Ohio, April 24, 1885.

Imported TUNISIAN Queens

at the same prices as imported Cyprians and Syrians. See back numbers. Tunisian queens are bronze color; Lees are darker than common bees, and far better honey-gatherers.

9d FRANK BENTON, MUNICH, GERMANY.

ITALIAN BEES AND QUEENS.

Full Colonies and Nuclei. By the pound, after June 1; Southern-bred queens after May 15.

9 E. A. GASTMAN, Decatur, Ill.

THE SUCCESS FOUNDATION + FASTENER.

"Takes the cake; the fastening is a complete job, as I never saw it before." Chas. E. Muth, Cin., O.

Correspondence with supply dealers solicited.

OLD TYPE FOR SALE.

We have still on hand 76 lbs. of our old nonpareil type for sale. For a sample of it, see any number of GLEANINGS previous to May 15, 1884. Also 17 lbs. of Italic, if desired. As it is all packed, we can not divide either lot. The Roman includes 5 lbs. and over of "logotypes," that is, the words *the*, *and*, *that*, *ing*, *think*, etc., are made all on one body, thus facilitating composition. We offer the lot at 20 cts. per lb. A. I. ROOT, Medina, Ohio.

1879. ITALIAN QUEENS. 1885.

For Italian queens in their purity, and that can not be excelled; Comb Foundation and supplies generally, send for circular. Untested queens, \$11.00 per dozen. T. S. HALL,
7-11db Kirby's Creek, Jackson Co., Ala.

KIND WORDS FROM OUR CUSTOMERS.

OUR SECTIONS OF 1885.

If your section boxes are not the best in the world, they certainly are the best I ever saw. They go together better, and I can keep them square, when they are together—a thing very much to be desired.

A. W. CHENEY.

Kanawha Falls, W. Va., May 11, 1885.

LOWER FREIGHTS.

The goods you sent me arrived here the sixth inst. all right. I am much pleased with them, and the freight (\$5c.) was very moderate, so I can afford to order goods of you again when needed. Bees all alive.

JOS. C. HAINES.

Mickleton, N. J., Mar. 9, 1885.

MAAMOTH CAVE

Your description of your visit to the Mammoth Cave is the best thing you have ever written. It is worth more than the price of GLEANINGS for the whole year. The children all read it, and are anxious for the next number to come, to get the rest of it.

MAHALA B. CHADDOCK.

Vermont, Ill., April 19, 1885.

GLEANINGS AS AN ADVERTISING MEDIUM.

Please drop my ad't, as I have all the orders I want at present.

OLIVER FOSTER.

Mt. Vernon, Iowa, May 11, 1885.

Please do not let my ad. appear again. I have refused hundreds of orders, and still the letters come, five to ten a day.

G. W. GATES.

Bartlett, Tenn., Apr. 22, 1885.

If you receive this in time to not let my advertisement appear in May number, please do so, if not, all right. I will pay for the one insertion in May. The demand for bees this season is too great for the bees.

DAN WHITE.

New London, Ohio, April 27, 1885.

THE FIVE-CENT GLASS-CUTTER FOR CUTTING PAPER.

The goods ordered from you came all O. K. The glass-cutter works as well for cutting patterns from paper as a pair of shears, when laid on a hard board or glass.

J. M. PETERS.

Bleeker, N. Y., Apr. 13, 1885.

[Thanks, friend P. Our painter has just made use of one of these glass-cutters for cutting out his stencils, and finds them away ahead of a knife.]

SOME KIND WORDS IN REGARD TO OUR MANNER OF SHIPPING QUEENS.

The imported queen which you mailed the 27th of April was received last night, introduced to a full colony this forenoon at 9 o'clock, and this afternoon at 6 o'clock she is doing a fair job of laying. I am very much gratified by the excellent order in which she was received. The bees all looked as if they had been caged only a few hours.

The first imported queen which you sent me several years ago has never had her equal in my yard, both as to the working qualities of her bees, and also their docility and markings.

Kansas City, May 1, 1885.

E. M. HAYHURST.

KIND WORDS IN REGARD TO GLEANINGS.

A great number of kind words have come in regard to the way GLEANINGS is managed, especially in regard to its talks on religion as well as bees. It would be altogether out of the question to think of giving place to these, and, in fact, I have thought best to omit one article from friend Hutchinson himself, as I think the space may be better occupied. I have thought best, however, to give place to the following:

My Dear Friend Root:—I have just read the article from friend H. on page 309, and am greatly surprised at the way he comments on the way GLEANINGS is edited—he is generally so level-headed. He says, "I have heard many others express similar views." Locality may have something to do with it—he certainly could not say that of this locality. I prize the Home Papers very highly, as do many of my neighbors, to whom I lend the paper. The piece in Mar. 15, on borrowing, etc., was read in our Good-Temper Lodge to an interested audience lately. Friend Root, you are doing a good work, and let nothing turn you from it. There is not enough of religion in our general business—that is a great lack of our time. I often think of one of Paul's messages, where he says, "Whether therefore ye eat, or whether ye drink, or whatsoever ye do, do all to the glory of God." Which means that the glory of God should be in, over, and above all our temporal business; and so I say, go on; give us Home Papers and religious thoughts. I should like to write you a long letter, but I know your time will not allow it.

C. W. COSTELLOE.

Waterboro, Me., May 9, 1885.

[Very likely GLEANINGS has sometimes omitted things of much importance, to give place to other matter of very little general importance, and I am going to try hard to profit by the kind criticisms I have had from time to time, from others as well as friend H., always keeping in mind, however, that seeking the kingdom of God and his righteousness is, at least to my mind, the first duty before us all.]

CONVENTION NOTICES.

The Mahoning Valley Bee-Keepers' Association will hold its next meeting at Newton Falls, Ohio, on Thursday, May 28, 1885.

E. W. TURNER, Sec.

The Bee-keepers' Association of Central Illinois will meet at Bloomington on July 15th, at 10 o'clock A. M.

WM. B. LAWRENCE, Sec.

Bloomington, Ill., April 30, 1885.

The 2d annual picnic of the Northern Mich. Bee-keepers' Society will be held at the apiary of F. A. Palmer, one mile west of McBride, Thursday, May 28. Teams will be at the depot in the morning to convey those coming on the cars to the grounds, and also return them in time for the P. M. trains home. Hot tea and coffee will be served in abundance, and all friends of the honey-bee are cordially invited. Remember the good time we had at Ionia last year, and come and let us compare notes.

McBride, Mich.

F. A. PALMER, Sec.

FRADENBURG'S RABBITS.

I have now 175 ready to fill orders, and shall have more in due season.

A. A. FRADENBURG,

Port Washington, O.

SECOND-HAND FOOT-POWER SAWS.

We have, subject to our order, three Barnes foot-power buzz-saws, which we have taken from parties whose business has enlarged so much that they have no further use for them. They are all nearly new, in good order, having all the latest improvements. We will sell them for one-fourth less than the regular retail price; that is, we will sell a \$49.00 saw for \$30.00.

A. I. ROOT, Medina, Ohio.

Decline in Sections.

UNTIL further notice, the regular Simplicity sections will be \$4.50 per 1000; 10,000 or more, \$4.00 per 1000; 100,000 or more, \$3.75 per 1000.

HONEY COLUMN.

CITY MARKETS.

ST. LOUIS.—Honey.—There is no change to note in our honey market. Quote extracted, southern, 14½c; 3½c. Comb honey, no choice white clover in market. A little inquiry for small pkgs. at about 16c in nice order. Dark not wanted. *Bee-swar*.—A little weaker. Orders scarce; 27½c. If demand improves, market will go higher.

May 9, 1885.

W. T. ANDERSON & Co.,
104 N. Third St., St. Louis, Mo.

CLEVELAND.—Honey.—The market is remarkably quiet just now, none moving; prices are unchanged; 14½c for best white 1-lb. sections; 12½c for second quality, and 2-lb. sections. Extracted not wanted. *Bee-swar*, 28½c. A. C. KENDEL.

May 12, 1885.

115 Ontario St., Cleveland, O.

DETROIT.—Honey.—The honey market is well supplied, and the demand quiet. One-pound sections, 12½c. A. B. WEED.

May 12, 1885.

KANSAS CITY.—Honey.—Demand for choice white comb, in ½, 1, and 2 lb. sections, good, and prices fairly maintained; ½ lb., 15½c; 1 lb., 13½c; 2 lb., 10½c. Extracted, slow at 50½c. *Bee-swar*, 25½c. According to quality. We want some ½-lb. sections of comb honey, and will need some more nice white 1-lb. sections. Shall be pleased to hear from parties having any.

May 11, 1885.

CLEMONS, CLOON & Co.,
Kansas City, Mo.

CHICAGO.—Honey.—Comb honey sells slowly; not much change in prices. For a fine quality, 10½c. is about the range. Canded comb honey is unsalable. Extracted, 6½c. *Bee-swar*.—Dull at 28c. for best.

May 12, 1885.

R. A. BURNETT,
161 So. Water St., Chicago, Ill.

MILWAUKEE.—Honey.—This market for honey is without any particular interest; very little demand, and prices almost nominal. Maple sweets now supply the demand for those who eat much honey. Will quote 1-lb. sections, white, 13½c; large white sections, 10½c; extracted, in pails, 8½c; extracted in kegs, 7½c.

May 12, 1885.

Bee-swar.—Pure and yellow, 30½c; dark, 20½c.

May 12, 1885.

A. V. BISHOP,
142 West Water St., Milwaukee, Wis.

EASTERN QUEENS.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

QUEENS FOR SALE.—Hybrid queens, 50 cts. each; black queens, 25c each, from June 1 to Oct. 1. Safe arrival guaranteed.
R. H. BAILEY,
7-11db P. O. Box 81, Ausable Forks, Essex Co., N. Y.

I have about 6 hybrid queens that I will take 50c each for. Address at once,
A. B. JOHNSON, Elizabethtown, N. C.

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 5 lines, and you must say you want your ad in this department, or we will not be responsible for any error.

WANTED.—To exchange 4-piece dovetailed sections for bees or Italian queens.
W. S. WRIGHT, Battle Creek, Mich.

WANTED.—To trade L. hives complete, for comb honey, sections full of fdn., or chaff hives, for bees or fdn. mill.
JOHN C. STEWART, Hopkins, Nodaway Co., Mo.

WANTED.—To exchange a \$35.00 aquarium for a good medium-size foot-lathe. A Shipman's Demas No. 4, or a Barnes No. 4 preferred.
JAS. H. ANDRUS, Almont, Lapeer Co., Mich.

WANTED.—To exchange a good Excelsior printing-press, self-inker, chase 3x5, with 7 fonts of type, with furniture to match, for young bees, any color. Address
SAMUEL HEATH, Rimer, Armstrong Co., Pa.

WANTED.—To send a sitting of 13 choice Brown Leghorn eggs for Italian queens in May or June; will send the eggs at once, and queens may be sent when ready.
C. L. BROOKS, Deansville, Oneida Co., N. Y.

HELP FOR THE SUFFERERS.

The following friends have agreed to furnish bees and queens at low prices, for the benefit of the friends who have lost badly during the past severe winter. In consideration of this, they are allowed to give the following notices once free of charge. As will be noticed, the prices are more or less lower than our regular advertised rates.

10 lbs. of Italian bees for \$12.50. Full colonies in Simplicity hive, or brood-chamber of Manum hive, for \$8.00.
W. H. PROCTOR, Fair Haven, Vt.

During the months of May, June, and July, I will sell 2-frame nuclei, with untested Italian queen, for \$2.25; 3-frame nuclei, with untested Italian queen, \$2.75. Italian bees by the lb., the 1st of June and after, \$1.00. Satisfaction guaranteed. Address
A. B. JOHNSON, Elizabethtown, Bladen Co., N. C.

On and after May 15th, and until further notice, I will sell nuclei, with black or hybrid bees and queens, just as they happen to come, at \$2.00 each, to contain queen and one frame with adhering bees, and honey for the trip; and if the friends wish to add 50 cents more I will send a frame containing as much brood as can be spared at that price, and at this time of the year. The above sent in light shipping-boxes, and perfect satisfaction guaranteed.
C. W. SLEIGH, Richland Center, Wis.

Vol. XIII.

MAY 15, 1885.

THE A B C OF POTATO CULTURE.

A "TALK," SUGGESTED BY READING IT.

FRIEND ROOT:—We had so thoroughly enjoyed the writings of Mr. Terry, in the *Country Gentleman*, that, the moment we saw that his "potato-book" was "out" we sent for it.

It came last evening. We found it so interesting, that, when the little girls were asleep, we "commenced over again," and read aloud to Mrs. H. Before retiring we had read it about half through. After retiring we "talked" until Mrs. H. said, "What is it keeping us awake? is it that potato-book?"

"I was just thinking the same thing," was the reply.

This morning we were up at daylight: the reading is now finished, the book sent to Mr. Heddon, with the request that, after reading it, he send it to Prof. Cook. Friend Root, you are perfectly safe in offering to "trade back" with those who think, after reading the book, that they have not got the worth of their money. What a wide-awake, *thinking* man is Mr. Terry! What a bee-keeper he would have made! What an *any thing* he would have made! Why can not each and every person in this world find some work for which he and his surroundings are specially fitted, then *stick* to this one thing, and put their whole *being* into it? The reading of this book has aroused us wonderfully. What, to become a potato-grower? Oh, no; nothing of the kind, but to try to become a better *bee-keeper*. We long ago adopted the same course as has Mr. Terry; i. e., we don't make our butter, nor keep

pigs nor chickens, much to the wonderment and against the advice of many neighbors. We can raise our butter, eggs, chickens, meat, "potatoes," etc., much more easily and cheaply in the apiary.

We should not forget, however, that everybody is not constituted alike. You, friend Root, were once "crazy" to keep bees, then to raise carp, then strawberries; and after reading Mr. Terry's most excellent little work upon potato culture you are "crazy" to raise them; while the reading of it makes us crazy only to do something to make of bee-keeping a more safe and profitable business. The wintering trouble is the one great obstacle at present; when this is overcome (and we have full faith that it will be), then will bee-keeping become more of a specialty than ever. Features and factors that now pass unheeded will be most forcibly brought to our notice; as, for instance, the idea put forth by Mr. Heddon; viz., "How shall we exhaust the field with the least expenditure of capital and labor?" We shall learn to manipulate hives instead of frames. The Heddon method of preventing after-swarming is an illustration of our meaning. Then we shall handle apiaries as we now handle hives. Honey will be cheap? Of course, it will; but the men who are then engaged in its production will be more prosperous than at present. They can afford the machinery, fixtures, and appliances to handle several large apiaries, the same as Mr. Terry can afford expensive potato-raising machinery; and it will give them the same advantage over the bee-keeper with a few colonies that Mr. Terry has over the man who raises an acre or two of potatoes. There is *something* in which each one can excel; that, let him do. We sincerely hope,

friend Root, that you will sell thousands and thousands of this little work, although the buyers will have the best end of the bargain. We wish that every one who is now engaged in some occupation that is capable of profitably absorbing all his time, talents, and money, but is thinking of adding bees, or any thing else, to his regular occupation, with the hopes of making money thereby, might read the chapter upon "Potato-growing as a Specialty." That one chapter is, in our opinion, worth \$5.00—no, it is priceless—to one who has never given the matter much thought.

The reason we sent the book to Mr. Heddon is, that he might enjoy seeing his views upon this subject (specialty) so well expressed; and we sent it to Prof. Cook because he has *opposite* views, and we hope that a perusal of this chapter might cause him to at least modify them. Prof. Cook may not be *opposed* to specialty, but we have never known him to argue as does Mr. Terry; in fact, it seems to us, that he always takes a nearly opposite view.

We must not omit to mention that Mr. Terry *pays* the children for "picking bugs." How much better than *compelling* them to do unpleasant work! how much easier and more pleasant for the children! At "our house" the little girls earned nearly enough by "whacking together sections," as they call it, last winter, to buy each of them a "little red rocking-chair." His views upon raising a first-class article are exactly in accord with our own, as will be seen by comparing them with those given in our article on raising first class honey. Those who raise potatoes should get the book, and learn how to do better, or else quit the business: those who do not, should get it as a "brain-tonic."

W. Z. HUTCHINSON.

Rogersville, Mich., May, 1885.

Why, old friend, what ails you? I was afraid to send you a copy of our book on potato culture, because I knew you were so much in favor of specialties, and I was afraid you would not want to take time to read a book all about potatoes. It did occur to me, that there were many things in it that would please you, but I had no idea that you and your wife too would drink it all in, as you seem to have done. Your concluding sentence hits the spot exactly, and it has seemed to me every time I read it, that it is good for everybody as a "brain tonic." I have thought of a hundred different friends to whom I wanted to send it, but I was afraid that they would think that I and my books were a nuisance. I do love to see these outdoor rural industries developed and unfolded, and it has sometimes almost seemed to me that the millennium was coming along this line, by having people waked up to the possibilities of these homely, every-day things all round about them. Just think of the idea—making the raising of potatoes a new industry, and the corner-stone, almost, of a new science! Yes, it struck me, too, that we bee-keepers need just such talks and teachings as friend Terry is capable of giving. The farmers of the State of Ohio, in fact, decided upon this some time ago; for they bid fair to keep him employed most of his winters in talking to the farmers of the State at our excellent farmers' institutes.

What can be more homely or commonplace than a potato? and yet how odd it

seems to think of a talented and educated man making the potato his life study!

"DRY FECES." (?)

PROF. COOK IS STILL VERY DECIDED IN REGARD TO THE MATTER.

MR. EDITOR:—This "dry feces" matter is going to be a veritable "wheat into chess" controversy in apiculture. Science may kill theory so dead that there is not enough of the corpse to decently bury; yet, like Banquo's ghost, it will spring to life again, and resurrected, too, not by ignorant men, but by those whom we should expect would be too wary to be carrying about an old theory never possessing any vitality, and, moreover, killed dead time and again.

Recently I have received these "dry feces," indirectly from Mr. Cornell twice; from W. F. Clarke, James Heddon, G. M. Doolittle, etc. What are they? Mostly beeswax, often containing pollen, and frequently wood, paper, paint, indeed any thing that the bees may attack with their jaws in the attempt at removal.

Mr. Editor, did you ever try to remove—in the absence of a pocket-knife—bitter bark from a twig, or any other ill-tasting substance, with the teeth? What did you do? You spit it out, of course. Well, you may not like to be told so, but that was the exact parallel of "dry feces." You remember that bite of comb with its bitter bee-bread, and how you cast it forth with spitfire-like energy. You extruded "dry feces," not only in origin, but in very nature—wax and bee-bread.

As will be seen in the paper that I read at Lexington, Ky., before the N. A. B. K. A., I have examined this subject with glass, test-tube, and crucible, and each and every test spoke the same conclusion—rejected pellets formed by gnawing of the bees. They taste like wax, or wax and bee-bread; melt easily like wax; dissolve quickly in alcohol or ether, but not in water, are seen to be wax often containing pollen grains and miscellaneous substances, when viewed with the microscope; blaze up when put in a flame, with the odor of wax, and sometimes of burning nitrogenous substance. I have these pellets now that contain fibers of wood as long as a bee. Surely this would have been a pretty irritating cathartic.

I have dissected hundreds of bees, and dry excreta is *never* found. The real excreta of bees always breaks up readily in water—there is no wax in it—forming a yellowish or light-colored mixture. This is true if we take them even when dry and hard, after the bee has been long dead. These gnawings will never break up in water. I will tell you, Mr. Editor, where you will find these gnawings piled up quickly and high. Where a weak colony is robbed. The bees in robbing cut off the cappings, rejecting the gnawings, and the weak bees are too reduced or too occupied to carry off the chips, and so the "chips" pile up high under the combs. I have just seen such a case, and could gather a table-spoonful of gnawings just like those received from W. F. Clarke, and all made or dropped in a few hours.

Some harder darker pellets from Mr. Cornell seem like feces. I have never seen such in bees, and have never found any such under bees in winter or spring; yet that bees, like other animals, may, upon

occasion, get costive, and void impacted matter, is possible. That they do so in our best wintering is certainly not true so far as I have examined.

Let brothers Cornell, Tinker, Clarke, or any other doubting Thomas, investigate this matter fully, and he will doubt no longer. No wonder the late Mr. Quinby, and Mr. Abbott, of England, thought these feces. I felt sure, when I just trusted to my unaided eyes; but full investigation showed that I was wholly wrong. Shut bees up in summer, and these pellets will fall thick in the hive, as the bees gnaw hard on wire gauze and wood, in hopes to escape.

A. J. COOK.

Agricultural College, Mich., April 25, 1885.

HELP FOR THE SUFFERERS.

SELLING BEES BY THE POUND AT LOW PRICES.

I HAVE received a shower of letters and postals, asking questions about my bees, such as these; "Have you any foul brood among your bees, and did you truly buy imported stock to breed from?" "It must be your bees are in poor condition, you advertise at so low figures." "Send me 30 swarms C. O. D.; and if the bees are all right, and have queens all right, I will keep them."

Christopher Grimm, of Jefferson, was here to see me the 4th day of May, and he went out among the bees and he said he never saw so many swarms together in such perfect condition.

And now, friend Root, this 9th day of May I send you by express one of my pure Italian swarms, daughter of the imported queen I bought of you in 1883; and what I wish of you is to examine this swarm, and pass judgment on it, and then insert a slip in GLEANINGS, as to whether they are good or poor, or whether it is worth \$5.00 dollars or not; and after deducting all expense, you may give me credit for what you think they are worth, or you need not allow me any thing. I leave it to your judgment. The reason I send this swarm in this way is, it will help people to have more confidence in my honesty. I want to sell my bees, for the reason I am confined to the house with a chronic difficulty.

J. R. REED.

Milford, Wis., May 9, 1885.

Friend R., I knew you would have a shower of applications, and I hope you have bees enough to fill all your orders. By the way, where advertisers offer bees below usual prices, I think it would be a good thing for them to state how many colonies they have to draw from, so that applicants may calculate what the probabilities are of their shipper being overrun with orders. In our price list we have stated that we can not send queens C. O. D. This C. O. D. is a bad business any way, for the reason that there are always more or less people who will be short of money, or change their minds when the goods get to their station. Bees are perishable property, and it is a good deal of work to put them up ready for shipment, to say nothing of express charges both ways. Certain kinds of goods can be sent C. O. D. without much difficulty, especially where there is considerable value in very small compass. A watch, for instance, may be sent to the purchaser, and he may be allowed to examine it before paying; but to think of doing the same thing with a

swarm of bees is out of the question. The shipper ought to have the cash in his pocket, or an order from some good reliable man, before he even puts them up.—I am much obliged indeed, friend R., for the sample colony you shipped us, but I am sorry you thought best to take all this trouble.—In regard to the foul brood, it is understood that no man advertises bees for sale, or offers them in any other way, who has foul brood in his apiary. If any one who reads the bee-journals knows of any such thing being done, he should notify the editors at once, and have it put down.

In regard to whether the bees be Italian or hybrids: When anybody buys bees by the pound at half the usual price, or less, he certainly ought not to ask whether they are blacks, hybrids, or Italians; and, in fact, at this season of the year, when bees by the pound are bought for building up colonies, it does not make any great difference what race of bees they are, for the queen will fix the purity of the colony in a very short time herself. We have nothing but pure Italians in our apiary, and do not expect to send out any other kind of bees by the pound; but our prices are very much higher than what you put them, friend R.

Later.—The bees are at hand, and we call them fine Italians, and worth a good deal more at this present crisis and season than what friend Reed advertises them for.

TOBACCO COLONY.

GIVING UP TOBACCO AFTER USING IT FOR FORTY YEARS; WHAT A LITTLE GIRL CAN DO.

MY father takes GLEANINGS, and he keeps bees. He has 48 colonies. He has been feeding waste honey, but he carries it about three hundred yards away from his apiary, to prevent robbing. We live on a farm. I go to school, and like my teacher very much. Grandpa and grandma live with us. Grandpa has used tobacco for forty years, but has not used any now for three months, and says he is not going to use it any more. Don't you think he deserves a smoker? I am going to have my flower-garden close by the bees this summer. I have already set some honey-suckles and jasmine to make shade for them. We had lots of honey-dew honey last year. I do not like it. I am starting some watermelon-plants for early use. I fill an egg-shell, and place the shells in a box of dirt; and when they are nicely up, loosen the shell from the dirt, and transplant to the garden, without disturbing the roots. They will not stop growing. MAY SIGLE, age 12.

Butler, Bates Co., Mo., April 19, 1885.

To be sure, your grandfather ought to have a smoker, friend May, and I am very glad of the opportunity of sending him one.—Your idea of starting watermelons is a real good one. We have been at work on the same thing with thin paper boxes, but the weather has been so cold we could not set them out, and our melon-plants got pot-bound.

I am just commencing in bee-keeping, and I learned from Mr. Wood Trenor that you would give any one a smoker who would quit chewing tobacco, and I will say this: If you will send me one I will

quit; and if I do not, I will send you the money for it.

DOCK CONNOR.

Madisonville, Texas.

Friend C., the smoker was sent you some time ago; but we now notice that you use the expression *quit chewing*. In offering a smoker I always use the term *using tobacco*; for I can not see that it makes any difference whether one chews or smokes—it is all tobacco-using. Now, if you did not mean that you would give up the use of tobacco in every form or shape, we trust you will be gentlemanly enough to return the smoker, or pay for it.

I have quit chewing tobacco; chewed only three years. It would kill me to chew three years more. If you think you can give me a smoker, send one. If you can't give one, send one by mail, and I will send you the money.

J. G. MILLS.

Moulton, Texas, Jan., 1885.

Friend M., there will be no charge for the smoker, providing you give up the use of tobacco in every shape and manner, as mentioned above.

I have used tobacco for several years. On Jan. 1 I resolved to abandon it, and threw away my pipe, and kept good my resolve so far. If your offer of a smoker is yet extant, please send me one. I wish it as a reminder of my promise; and should I fail, I will pay for it, and send you a new name for GLEANINGS besides. The battle will be hard, but I mean to win it, asking God to help me.

Dahlgren, Ill.

F. C. VANDERVORT.

I am (or, rather, *have been*) a tobacco-smoker for ten years. I have often thought I would quit using the filthy weed, and at last made up my mind that, with God's help, I would stop. If I am entitled to a smoker, you may send me one. If I commence using tobacco again, I will pay you for two. Not many bees in this part of the country, but what there are do well. Honey sells for 20 cents per lb. for extracted, and 25 cents for comb honey.

Hepler, Kansas.

M. A. TIMBERMAN.

FROM A BROTHER WHO PREFERS TO PAY FOR HIS SMOKER, SO IT WILL NOT BE ANY MORE A REMINDER.

I was out yesterday, although the mercury was at zero, and sold a few pails of honey; and by borrowing some I am able to inclose \$6.00, which please find. After squaring my account you will take the rest to pay for that tobacco-smoker I had of you. I find that it is more of a reminder of the fact that I have received your goods without paying for them than any thing else, and now I do not feel that I have taken something for nothing.

Carlton, Mich.

J. S. COLE.

Friend C., we thank you for paying for the smoker, but we hope it is not because you have gone back to tobacco again. It looks a little that way, although you do not say so.

A BROTHER WHO FEELS HE NEEDS OUR PRAYERS.

This is the first time I have addressed you. I have had a hard battle with tobacco since Christmas. Will you pray for me, that I may be fully able to abstain for ever, God being my helper?

Summersville, Pa.

ISAAC A. CLARK.

Most surely I will, brother C.; and may the kind Father help, strengthen, and sustain you.

ANOTHER VOLUNTEER.

I think I will lay claim to one of your smokers. I thought I would quit using tobacco before asking you for one. I have a swarm of bees, and I am also running a potato-ranch, and I am all alone; so if you will send me a smoker I will pay you for it, if I use tobacco in any shape or any form.

WM. HILDERBRAND.

San Bernardino, Cal., Oct. 19, 1884.

My daughter's husband is a young man 24 years of age; he is going to try bee-keeping. He has borrowed GLEANINGS to read. He likes it very much, and is going to take it this year. I have been trying to have him break off smoking. He says he will not smoke again if I will write for a bee-smoker. If you think it worth while to send him one, if he smokes I will send you the money for it. This is from a great tobacco-hater.

MRS. H. N. FOSTER.

Richford, Vt., Dec. 16, 1884.

I used tobacco 28 years. Over four years ago I quit, and have in no way used any since GLEANINGS reminded me every number, till at last I overcame the habit. If you think I deserve a smoker, send one to me.

ISAAC EBY.

New Germantown, Pa.

I have given up tobacco. Please send smoker. I will pay you for it if I take up the habit again.

Gonzales, Texas, Feb. 23, 1885.

M. BROERS.

FROM A FLORIDA FRIEND.

If I again return to the use of the weed I'll consider myself your debtor for the price of the smoker.

T. C. WAGGH.

San Antonio, Florida, Nov. 29, 1884.

I would say in regard to tobacco, that I have quit chewing and smoking, although never an habitual smoker or chewer.

CHAS. BLATHERWICK.

Bryan, Texas.

I happened to see where you promise a Clark's smoker, or give it as a reward to all who abandon the use of tobacco. This I have done, after using it 24 years. If I am entitled to the smoker, please send and oblige.

R. F. CARY.

Poca, Putnam Co., W. Va.

Bro. Richard Henderson, close by me, has been moved to quit using tobacco; says it is a fight, but is determined never to use it again. I told him of your plan. Should you see fit to send him a smoker, send it to Richard Henderson, Benton Ridge, O.

Stanley, Ohio.

S. H. BOLTON.

Three months ago I laid tobacco aside, after being its slave 20 years. I promise that, if I ever break over and rob the tobacco-worm of his rations in any form I will pay you \$1.00 for the same. I have five stands of bees in good condition. I like the L. frame the best.

WILLIAM DUCKWORTH.

Greenwood, W. Va., April 22, 1885.

FOR JESUS' SAKE.

My father is 57 years old, and has quit tobacco after having used it 45 years. He quit it for *Jesus' sake*.

W. D. GILLILAND.

Abatis, Mo., March 11, 1885.

For Jesus' sake! That is the last item on this page, dear friends; but, does it not sum it all up? Not only this little page of print, but these pages of our life, the lives that you and I are living?

THE CALIFORNIA-SUN-STRAINER.

A CHEAP WAY OF MAKING AN AUTOMATIC AIR-ARRANGEMENT FOR RENDERING WAX.

THE following, from the pen of friend Muth-Rasmussen, whose portrait we gave on page 193, we have taken from the *Pacific Rural Press*.

As I have never seen it mentioned in print, I will here give a description of this valuable apparatus, which ought to be found in every apiary in the land.

The sun-strainer is a triangular box, something like a corner cupboard laid down on its back edge. It is lined with tin, and covered with one or more window-sashes. A sun-strainer, covered with a sash of six 10x16 lights, is large enough for an apiary of 100 colonies, run for extracted honey. This sash should fit bee-tight, to prevent bees from crowding in, which will invariably result in their death, as either the heat will kill them, or they will worry themselves to death trying to get out through the glass. About half way between the cover and bottom edge is placed a strainer-plate, made of sheets of tin, perforated with $\frac{1}{8}$ -inch holes, three-quarters of an inch apart, and fastened to a light wooden frame under the tin. Wire-cloth should not be used for the strainer-plate, as it is difficult to

the cappings goes through the tube into the honey-room, where it is collected in a can or separate tank. The sun-strainer should therefore have a slight inclination toward the house, that the honey may flow freely and not remain standing between the different layers of wax formed, as more cappings are added from day to day. The honey will be slightly darker than the extracted honey, and should be kept separate, to be either sold as a darker grade or kept for stimulating or feeding the bees. It will be a good policy to keep on hand half a ton or more of such honey, as it may save the bees from starvation during one of our not unfrequently dry seasons.

Most of the refuse will remain on top of the strainer-plate, from which it can easily be scraped off, while it is warm. If the plate becomes clogged, the holes may be opened with a carpenter's compass or similar tool. This should be done when the plate is cold. The wax should be cut out with wooden paddles, choosing a time when the wax is tolerably soft. Never use a metallic tool for this purpose, as it is liable to cut the tin lining, and it is almost impossible to mend such an injury after the tin has been coated over with wax. In very hot weather some of the wax will run through the tube and partly fill it. When the sun-strainer has been emptied, the extension tube should be taken off and the wax pulled out of it. If the wax sticks, the tube may be laid in water, which will dissolve the honey and loosen the wax. The wax is then placed in a tub of water and afterward re-melted. It is hardly necessary to say, that the glass should be kept bright, clean, and free from dust, in order to have the best effect. The sun-strainer should be housed during the winter, but the frame may be left in its place all the year round.

ANOTHER STYLE OF SUN-STRAINER.

Is built fast to the wall, has a sloping glass cover, and, under this, a close-fitting shutter, hinged at the top. Through the hole in the wall, closed by this shutter, the sun-strainer may be filled and emptied from the inside of the honey-room. This is an advantage when bees are inclined to rob.

FORMER USE OF THE SUN-STRAINER.

When I first learned the bee-business, extractors were not known on the Pacific Coast, and, as far as I know, I was one of the first, if not the first bee-keeper in California, who imported an extractor from "the States." It was my old friend and benefactor, Mr. Thomas A. Garey, of Los Angeles, who drew my attention to the advertisement of an extractor in the *American Bee Journal*, specimen copies of which were occasionally sent him; and to him justly belongs the honor of the first introduction of the honey-extractor into Southern California. Previous to that event, all honey not sold as comb honey was strained by means of the sun-strainer. The sun-strainers were, therefore, then of necessity very large, the one with which I first worked being 7 feet 6 inches long, and covered with a heavy door of glass. It had a melting capacity of a ton a day in hot weather. As all the honey was thus strained, the term "strained honey" became fixed in the minds of the public, and has been slow to give way to the newer term, "extracted honey." All the honey-comb was, of course, melted up with the honey, the whole as it was cut out of the supers being dumped into the sun-strainer in a promiscuous mass, and an immense amount of wax was made at that time.

Considerable has been said about these sun-strainers, but I have not learned of anybody who has made them a practical success here in the States, unless it is friend Poppleton, whose articles were given, with an illustration, on page 521, Sept., 1883. Wherever

THE CALIFORNIA SUN HONEY-STRAINER.

clean, and easily gets clogged or broken. A semi-circular handle is soldered to each end of the strainer-plate. Underneath is placed four little tin brackets, soldered to the vertical ends of the sun-strainer, two at each end, to prevent the strainer-plate from tilting sidewise. In one of the ends of the sun-strainer, and as near the bottom as possible, is soldered a $\frac{1}{2}$ -inch tube, four inches long. Another tube of the same diameter, a foot or more long, telescopes over the short tube, and goes through a hole in the wall into the honey-room. Some place the sun-strainer in a scaffold, standing apart from the house, but it is better to have it resting in a frame bolted to the south side of the honey-house, where the sun will strike it nearly all day. The sash should be hinged over the tube so that when it is raised it rests against the wall, where it may be fastened by a hook or other device.

USE OF THE SUN-STRAINER.

When the cappings have been drained sufficiently, they are placed on the strainer-plate, and the sun-strainer closed. The heat of the sun melts the cappings, and as soon as the wax gets below the strainer-plate it cools and forms a solid cake. The wax never gets overheated in this way. When made from new white cappings, it will always be of a bright yellow color. What little honey adheres to

the heat of the sun is sufficient, it will doubtless be not only a labor-saving institution, but it will give us a finer quality of both wax and honey than is usually obtained by means of fire heat or steam heat. The machine mentioned above seems very simple and easy to construct; and the idea of having it against the honey-house, so that the honey would run inside, is quite ingenious.

A LETTER FROM MRS. AXTELL.

SHE ASKS SOME QUESTIONS ABOUT THE WAY OUR BEES WERE PREPARED FOR WINTER.

DEAR FRIEND:—I should like to ask you a few questions about how you prepare your bees for winter, that they could come out a "booming" this spring. We have lost more than half of the 244 colonies we had last fall; now 42 marked good at Home Apiary, wintered in cellar, and 45 weak, many of which will have to be helped by brood or bees from the better colonies, or can not even save their queens at this late date.

At the Timber Apiary, only 8 good ones; about 30 that will barely save their queens. We find some dead every time we go through the hives; 38 left from the 125; we thought 119 would live, wintered in cellar. We knew they were in poor condition to winter last fall; but we were both of us in such poor health that we let them go.

I should like to ask how many combs per colony you leave in. Do you extract all the honey before feeding, and about how many pounds of sugar do you feed per hive? What month, and what time in the month do you feed for winter? Do you winter all out of doors? and do you sweep the snow away from the entrance? or if a hive seems clogged up, do you run a wire or stick in to clean out dead bees? Is it advisable to lean a board up in front of the hive, to keep the snow from covering the entrance, and let the snow alone? Would you shovel snow around the hives? How large an entrance do you leave open in winter? Do you extract the honey before feeding sugar syrup? What kind of a feeder do you use? Do you clip your queens' wings in the spring? We do not see that it hurts them any, and saves a good deal of trouble in getting them off the trees. Do you put an enameled cloth under your chaff cushions? If so, I should think it would not be porous enough to let the dampness pass off. Do you use the same oil cloth to put on top of the sections to keep the bees down? If so, is there not propolis enough on it to soil the sections? or do you clean the oil cloth, and how?

We had a circular sent us the other day by a company that makes oil-cloth ducking, etc., for sale. I wonder if you could not get it at reduced prices for bee-keepers to make covers to hives, as it would be so light, and not leak. Our hive-covers leak some, and we are thinking of getting the cloth and cover and paint.

Tell the girls that a part of the barrel of hats sent me were sent to the Indian Territory, and sold; the best were sold, and the money was used by that earnest missionary, S. R. Keams, to help build a church last year. This past year, more hats were sent him, and he is disposing of them to help build his third Indian church this coming season.

Of course, it is not all done by hat-work, but it

helps, and those given away also help. One of his Sabbath-schools he said was nearly half built up by the children who had been induced to come by the present of a hat. The rest of the hats were sent to Talladega, Ala., for a freedmen's school.

If your girls see fit to send me another barrel of hats I will see that they are put to a similar use as the last. I always give the donors credit for things sent, and ask them to acknowledge them.

My health has been very poor this past winter; and I am now not able to sit up any; but hat-work is God-given work, for me to employ the hours spent on my bed to further his work, and to help fill my life with sunshine and happiness in that I can do something for his needy ones.

Roseville, Ill., Apr. 25, 1885. MRS. L. C. AXTELL.

My good friend Mrs. A., I am very sorry indeed that your health is so bad again; and yet it seems wonderful to think of your working, day after day, while you are not able to sit up. If I should ever be confined to my bed, I think that is just what I should want to do—work. If I am correct, almost if not quite every summer, when the bees begin to get out and store, you soon follow suit. Surely, Mrs. A., you are able to employ some careful person to put your bees in proper order, are you not? With the precarious state of your health, it seems to me your first duty is to have some one with you on whom you can depend. In my own case, I scarcely lifted a hand personally to fix our bees for winter, and a great part of the colonies I did not look at, but advised and directed all through. We left from five to eight combs in a hive, according to the strength of the colony. We did not do any extracting at all, and the amount of sugar fed was dependent on the size of the colony. We did not weigh at all, but just kept feeding until the combs were solid slabs of sealed stores. The bees were crowded into a pretty compact cluster in the center of the combs, usually having a little patch of brood there when the feeding was finished. Perhaps their stores averaged from 15 to 20 lbs. per colony. We commenced feeding in September, and were all through by the middle of October. We winter our bees all outdoors. We never meddle with snow around the entrances at all. Several times last winter our apiarist was a good deal worried about it. I told him I was sure that snow over the entrances never did any harm. The loose chaff over the frames, with only coarse burlap to keep it from rattling down among the bees, made it impossible that they should suffer from lack of ventilation, no matter what happened to the entrances.—We did not run any wire or stick in the entrances to clean out the dead bees. The entrances were left open full width, exactly as they were in the summer. With chaff hives we never put any thing in front of the entrances to keep away the snow, or keep the sun from shining on them. I would not shovel snow around the hives, because it would be likely to create disturbance with the bees. If the snow falls around the hives, even so as to cover them all up, well and good; but I do not believe shoveling can be done so as to avoid disturbance.—We did not extract any honey at all, before feeding; but the rea-

son why we did not was that, having so many colonies in one locality (400 to 500), our field is overstocked, and they consumed pretty much all they gathered—honey-dew with every thing else. Selling bees constantly by the pound, as we do, tends to work up almost all natural stores into brood, leaving the way open for sugar feeding.—We use principally the bread-pan feeder, figured on page 32 of our price list. To keep the bees from drowning, a piece of cheese-cloth is laid loosely over the top. We do not clip our queens' wings at all. You know we rarely have any swarming, because we keep selling our bees by the pound to such an extent that a hive seldom gets sufficiently populous.—We do not use an enamel cloth for wintering—only the sheet of coarse burlap mentioned before. After putting on this sheet of coarse burlap we put about a peck of

O. M. BLANTON, AND THE PLACE WHERE HE LIVES.

A VIEW AMONG THE BEE-HIVES.

YOU remember friend Blanton, I suppose. He is the man who helped Bro. Jones play tricks on me when we were down in Cincinnati; said he would stop using tobacco; said he wanted a smoker, etc. Well, he got the smoker. By the way, I think he got several smokers. I should think he would need several, shouldn't you? Just look at his bee-hives. He is the man who has them stuck up on stilts, you know.

Dr. B. gave me the picture that I had the above engraving made from when we were in New Orleans. He had quite a lot of pictures, and I picked this out from among them. I asked him if it was because of high water that he stuck them up on stakes in

O. M. BLANTON'S APIARY. GREENVILLE, MISS.

loose chaff around the edges, making it impossible for the bees ever to push up, and so get around the ventilators in the cover.—We have not raised any section honey for some years, of any account.—We do not use any kind of oil cloth for hive-covers. Tin costs but little more, and we think it much the cheapest in the end.

I shall have to explain to our readers, that, some time ago, in response to a letter from Mrs. Axtell, we sent a barrel of ladies' hats, to be used in the mission work in the Indian Territory. These hats were old ones, such as can be found in almost anybody's garret. Mrs. A.'s explanation tells what became of them. Our factory hands will at once scrape up another barrelful or more; and if any of the bee-friends feel like assisting in the good work, Mrs. A. will give the required directions as to where they are to be sent.

that way, and he said no, it was only to have them handy. He is quite a big man, and I suppose it makes him red in the face to stoop over, so he has got all the bee-hives "histed up like." You notice he has lots of trees around too. Yes, and there is one stump. I do not like stumps; they bother our sulky plow. I guess, however, the doctor does not plow any around *that* stump. Sometimes his bees swarm and hang upon those trees. That is what he has that step-ladder for. Well, you see it takes an awful sight of legs to put legs on so many hives, and so he has two hives on one set of legs, in some places. I wish he would tell us if he likes them as well made that way. Come to think of it, I rather expected he would write a letter to go along with this picture; but may be he will send us one to be put in next time.

APIS DORSATA ONCE MORE.

WILL THEY BEAR DOMESTICATION?

FRIEND ROOT:—*Apis dorsata*, after staying for twelve days with me, has absconded, and I hasten to give you the results of my first experiment with this bee.

1. Why did the bees abscond? On examination of the comb I found about half a pound of brood had been jammed into a fold of the comb made, when putting the comb into the basket for transportation from the hills. It was smelling very rank, and this of itself was enough to drive them off, doubtless.

2. I am not sure they had a queen. Before I got them into shape, about a quart of old bees swarmed up on a limb of a tall mango-tree, and after two days they left. At first the entrance to the hive was too small, and I think they could not readily find their comb, and so left. The queen might have been among them.

3. Perhaps this bee can not be made to stay in a hive at all, yet I am not at all satisfied that this is the case, and shall not be without much more experience.

We have gained some knowledge by this experiment. The young bees, when first hatched, are long and slender, very graceful in their shape and movements, of a soft dark yellow, approaching brown, which changes as they grow older. The abdomen grows fuller, and black bands appear, until the bee appears much darker, not only on the abdomen, but all over. The head, however, at first changes to jet black.

As there was a very little unsealed brood when I got them, and all hatched out in twelve days, I judge the time from egg to bee is about 21 days, as with common bees. I have a swarm of the *Apis florea* under observation (this is a unicombee also). I am struck with many things in common in the habits of these two kinds of bees, and have an idea that the study of the *Apis florea* will show us how to manage the *Apis dorsata*. But much observation is yet necessary. The comb of the *Apis dorsata* left with me measures about 2 ft. long by 1½ ft. deep. The honey-comb and brood-comb are quite distinct. The honey-comb is placed always highest up on the limb of the tree on which the nest is built, and is called by the natives the "honey-chattei." It does resemble a native chattei not a little in shape. From this, which is on the right in my comb, the brood-comb extends to the left, new comb being added along the whole edge, from the honey-comb around to the limb again. The honey-comb is 3 inches thick in its thickest part, but built in a cylindrical form. The natives say they have seen this honey-chattei 6 inches in diameter. The cells are 1½ inches deep, and less as the slope changes. There are three honey-cells to the inch. This comb is beautifully white. The walls of the cells are almost transparent. Honey is also deposited among the brood, but it seems to be of a different kind from that in the honey-chattei.

The brood-cells are from ½ to ⅞ inch deep. The number to the inch varies from 4 to 4½, or 23 cells to 5 inches. The brood-comb varies a little in thickness, and is about 1½ inches, and is a light brown in color. These bees on the comb form one of the most beautiful sights in nature I ever saw. During their stay they built comb and brought honey and water, but they did not at any time work as if they

were happy. Just before leaving there was great running to and fro, and preening of wings and legs, preparatory to flight. Not more than half a dozen bees were left. I put one, just hatched out, on the alighting-board of an *A. indica* swarm, and she immediately marched in like a queen, and the bees all made way for her. I suspect they got over their surprise and slew her, but I have not seen any results of such punishment. So much for experiment No. 1 with *Apis dorsata*.

P. S.—Wife says I've no eye for color; that, when first hatched, the *Apis dorsata* are light orange, which changes to darker orange, and then the black stripes appear. She says you don't know what a *chattei* is, and perhaps she is right. It is a cylindrical vessel shaped like a rather flat onion, only it is open on top, and the edge of the hole comes a little above the vessel, and then flares back somewhat. It is, in fact, a jar. This shape proves a very curious feature in the *A. dorsata* comb, and, when filled with pure white honey, is a sight worth seeing.

A. BUNKER.

Toungoo, Burmah, March 18, 1885.

Friend B., these are matters of great interest to us, and I would suggest that you get another swarm of *Apis dorsata* and experiment with them further. If you are out any in the way of funds in accomplishing this, let me know, and I will indemnify you. I do not quite make out how it is that a single comb built on a limb is in a cylindrical form. If I understand you, the comb of the *Apis dorsata* is not much different in dimension of cells from our own honey-combs. The large cells you describe, I should infer, are drone cells or what we sometimes call "store cells." And, by the way, does the *Apis dorsata* have drones similar to ours?

THOSE FIVE COMBS, ETC.

MORE ABOUT THE "NO-POLLEN" EXPERIMENT.

ON page 232 friend Root seems to desire further knowledge regarding the experiment I gave on page 231. I took away all the combs the colony had, and gave them five clean empty combs, which were very carefully examined, to see if they contained a single cell of pollen, not one of which was found. This was done about Sept. 15th to 20th. I now fed them 2½ lbs. of sugar syrup each night for ten nights in succession, making 25 lbs. fed. As the queen was not laying at the time the combs were taken away, I examined the colony after feeding five days, to see if any brood had been started, for I have never known a queen to start laying, in this locality, after she has once stopped, by feeding them for that purpose, as friend Root, Prof. Cook, and others, claim they do with them.

A careful examination at this time revealed only sugar syrup, for neither eggs nor pollen was found. I again examined them on the morning of the eleventh day from the time I commenced to feed, at which time I found no eggs nor pollen, although a space was left in their combs for a brood-nest, or, as I call it, a nest to winter in. Hence the insinuation of Prof. Cook, on page 238, that I guessed at the matter, is groundless. Again, I examined the colony about Oct. 25th, when tucking them up for winter, and found them clustered in and about their winter-nest, with no brood, nor any that look-

ed like young bees; and I firmly believe that there was not an egg laid by the queen, nor a bee-load of pollen gathered by those bees after I commenced to feed them. As far as the getting of meal is concerned, which Prof. Cook spoke of, by way of accounting for the absence of pollen husks in their excrement, I think that is far fetched; for I never saw bees take meal in the fall, and much less when no brood was being reared.

Well, where did the pollen come from which friend Cook found? We will let him answer. On March 10th he writes me, after he had received a piece of comb I sent him, taken from where the bees had died, which, the reader will bear in mind, was taken from near the top of the comb, and not from where the bees would have had their brood and pollen last fall, had they had such, "I find that the white substance" (I supposed this to be chyme) "at the bottom of the cells is the web or cocoon of once larval bees. To this I find pollen grains attached. I find a little pollen at the bottom of the cells, which, to the unaided eye, seem entirely empty; also some under the honey (syrup) on the side of the comb which you cut off. I find pollen, which the microscope reveals, in almost every cell." Hence it will be seen that these particles of pollen were scattered about the bottom of all these cells when the combs were given to the bees; for how else could it get under the syrup where Prof. Cook found it?

It will also be noticed that he did not find any pollen, except by the aid of the microscope; and when this was brought into requisition he finds a little in almost every cell, thus showing that bees use pollen in other ways than by the cellful, or half full, as we usually see it.

Why I have been thus particular in going into the minutia regarding this experiment, is because it has a direct bearing on the pollen theory, as it is applied to our wintering troubles. If I had only this one case, we might call it exceptional; but since this colony died I have lost three other colonies of diarrhoea (two in the cellar), which had only sugar syrup for stores, as far as the unaided eye could see.

I am asked, on page 232, "Did the bees have dysentery badly enough when they flew out so as to spot the snow?" Well, if they could have flown, the snow would have been spotted, I assure you, friend Root; for all of one end of the frames, and one side of the hive, was all smeared over with this excrement, which had all the appearance of being the same identically with that "which we are familiar with;" while the stench was as bad as any I ever smelled; and this was the same with the other three colonies. In fact, sugar syrup has shown no advantage over natural stores with me; and I see in GLEANINGS, and the other bee-papers, that others have had similar experience.

Now in closing I wish to ask: If bees do have the dysentery, and die with it, where no pollen can be detected by the unaided eye, in the combs that are placed in the hive for wintering, can the no-pollen theory be of any benefit to the average bee-keeper? Again, if we must wait till the first of November before feeding our bees, for fear that they will put pollen in our clean empty combs which we give them, as Prof. Cook thinks my bees did, can the no-pollen theory be made practical? Our best apiarists tell us that September is the month to prepare bees for winter, so that their stores may be sealed, and

all is quiet early in the season. Once more: In the light of the above experiments, how are any, except thorough scientists, to know whereof they affirm regarding the "no pollen no brood" theory? and how does friend Root know but that his bees in his greenhouse and other experiments had many particles of pollen in their combs, but refused to rear brood from some other cause? Gentlemen, what do we know on these points, any way?

Borodino, N. Y., May, 1885. G. M. DOOLITTLE.

I think, friend D., we know something, even if we do not know it all, as yet. In regard to my experiments in the greenhouse, whether there was pollen remaining in the comb or not, I succeeded in having the bees rear brood and stop rearing brood at pleasure by meal feeding, and by stopping the meal feeding. I did this during every month of that winter, until I was abundantly satisfied that there was at least a close connection between the pollen and brood. Whenever they exhausted their stores of meal, brood stopped, or very shortly after. By the way, friends, will it not be best to drop this pollen matter—at least for the present?

THE LATE DISASTERS OF WINTER A BENEFIT IN ONE WAY.

ALSO A WORD IN REGARD TO THE VETERANS WHO DO NOT WRITE ANY MORE.

I GATHER from correspondence through Central Iowa, that fully 80% of the bees that have been wintered outdoors are dead. I can see but one good result in it. Many of the bee-keepers have persisted in keeping the *blacks*, and it's generally that class (here) that left them out, unprotected, and are now wondering what's wrong. I think the Italians will have but little difficulty in taking the lead from this on.

What has become of Mrs. Axtell, that we hear no more of her? Probably (as she is an invalid) she has been in the furnace of affliction, and writing may be a burden. Her articles are always laden with good things. And then there is Hasty. Since his splendid translation of Virgil, has he put his candle under a bushel? And then the funny man who usually writes about Mr. Duster, "Under the Box-Elders;" has he gone to Congress?

HOW TO MAKE A CAVE.

Will not some of your correspondents tell us just how is the best way to arch over a cave with some good material that is cheap and will resist decay? Wintering bees in properly ventilated caves, in this latitude, is the coming way. D. E. BRUBAKER.

Maxwell, Ia., April 23, 1885.

Friend B., I believe it is a fact, that more black bees have died, and do die, than Italians; but I do not think the blacks any less hardy; in fact, I have sometimes thought that it was the other way. But the reason is, I think, the one you have suggested.—Mrs. Axtell answers for herself in this present number. As near as I can find out, friend Hasty goes by fits and starts somewhat, like many others who have much talent for serving the people. I have been expecting every little while that he would take a notion to write some more. The same with Mr. Duster, of the box-elders. May be he has lost his bees, and has got sour, but

we hope not.—Your cave business is just what I have been studying about: in fact, I do not know but I should have had a small Mammoth Cave down by the carp-pond before this time, if it were not for that difficulty you suggest—getting something to arch over, to hold up the dirt. I am afraid of boards, because they would rot or break, and may be some of the children would get buried up. I wonder if the stoneware men can't make us a great big horse-shoe tile, big enough so we could walk in and carry in bee-hives. We could extend it as we wanted more room, and it would last for ever.

WIDE, OR BROOD FRAMES, AND SEPARATORS.

FRIEND HEDDON'S EXPERIMENTS AND CONCLUSIONS IN REGARD TO THEM.

I HAVE been one of the pioneer opposers of wide frames and separators. At one time I thought of separators as many now think of $\frac{1}{2}$ -lb. sections; viz., that they cut the surplus departments up too small; but I have learned better, and I have for several years publicly said that separators are no hindrance to the amount of surplus we may receive, if other fixtures are properly arranged. Such practical honey-producers as Dr. C. C. Miller, and Oatman Bros., persuaded me to again give separators a thorough trial, and two years ago I did so by making 350 wide-frame supers (one story or tier of sections high), and used these side by side and over and under 300 of our cases, all worked on the tiering-up plan. I used separators of both wood and tin, about 1800 of wood and 300 of tin. My apprentices and neighbor Shirley assisted me in using and testing them. I have also used about 40 wide-frame supers two stories high. I have done my best to give these fixtures a comparative trial for the past two seasons, and I have used them in such quantities as to give us a physical as well as mental education regarding their merits. According to my present light I must render the following decisions:

1. My case is the best style of surplus receptacle I know of, to use without separators, and admits of no improvement by me.
2. I would rather abandon separators altogether, than use them in two-story supers.
3. I do not think there is any system of using separators, equal to the wide frame, when used one story high.
4. I would use no system of surplusage (either for comb or extracted honey) that did not give me the advantage of tiering up.
5. I prefer tin to wooden separators.
6. There are many advantages in the use of separators, and many in the non-use of them, and each person must be governed by his own special circumstances.
7. Their use or non-use need not affect the quantity of surplus secured.

I mean to continue the use of separators, and I am now perfecting a different style of super which I think will aid us greatly in their quick and easy manipulation, as well as their usefulness.

I can not see why my case is called "the Heddon, or Moore case." There is scarcely the least similarity between them. Bro. Moore's does not incase the sections. It is a rack to hold them in place only, if I understand the description correctly.

Downagiac, Mich.

JAS. HEDDON.

PERMANENT EMPLOYMENT.

Friend Tisdale tells us the Secret of it.

"WHOSO COMETH UNTO ME, I WILL IN NO WISE CAST OUT."

ON page 139 you gave most splendid advice to those out of employment. Now, friend Root, that was just my case two years ago. I was out of employment, used tobacco, etc. I tried to get work, but failed. I got discouraged; did not care what became of me; but I got to thinking over one of your sermons which I had seen in GLEANINGS. I got right down and prayed to God to help me, and he heard my prayers, and I have tried to keep his commandments ever since, but failed in some instances. Now, a good many men could not stay more than a short time with this man I work for. They said he was too hard a master, and they told me so; but I did stay with him. Perhaps it was because he was a Christian and they were not; and, what do you think? With so many out of employment, to-day there were five of the best farmers of Richfield came to me and wanted to hire me, and have their men sent adrift. No, I told them I was going to "stick to the old lady."

Now, young men, those of you out of employment, put your trust in the Lord Jesus Christ; keep his commands; go into the country; work for 30 cts. per day; be honest; build up a character; stick to good principles; do as your boss wants you to, if it is nothing more than to knock down a smoke-house and build it up as well as you know how; and whosoever does this will never want for work, and after a while get the best of wages. Do right, young man. May this be your motto, your shield, and your might, for the world ever honors true courage in man. Then never be afraid or ashamed to do right.

A. H. TISDALE.

Richfield, Minn., Feb. 23, 1885.

Friend T., I think you have struck the true secret. The man who gets down on his knees, all alone by himself, and asks God to help him do right, will, if he is at all consistent, get up and go to work in a way that must win him plenty of friends anywhere. If he is working for Christ he is working for his fellow-men; and the Master has said, "Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me." If you are working for Christ you must be working for those around you; and this kind of service never fails to be appreciated, sooner or later. There are those who make a profession, who are out of employment. I know very well; but I have never yet failed of being able to find that there was trouble somewhere, when I got acquainted with such people. A man who insists on faithful, honest work, is often called by many a hard man, when he is simply a just man; but one who has the love of Christ in his heart should be able to get along pleasantly, even with a man who is a hard man. I have sometimes felt a good deal of pleasure in finding that I could, by an extra effort, get along pleasantly with those who have a reputation of being difficult and hard to please. And such little victories do one good; for if we get along easily with those who are difficult, we shall have no trouble with the rest of the world.

He that is faithful in that which is least, is faithful also in much.—LUKE 16 10.

MYSELF AND MY NEIGHBORS.

Thou shalt love the Lord thy God with all thy heart, and with all thy soul, and with all thy strength, and with all thy mind; and thy neighbor as thyself.—LUKE 10:27.

AMONG the piles of things thrown on my table, from our heavy mails, there came yesterday a little pamphlet. I picked it up and absently turned to the first page. The words I read startled me. I put it in my pocket this morning, and at breakfast I read it aloud to our family circle. The words took hold of every heart, I believe, just as they took hold of me; and if I am not mistaken, the glances that were exchanged indicated that the words went home to other hearts than mine. Do you want to know what were those words that gave me a start—yes, that startle me now, and trouble me, because they remind me that I am a guilty sinner in God's sight? Well, here is the little sentence:

I had been thinking how strange a thing it was that I disliked so many people, and liked so few.

The next words were right in the same line, and they make me even now catch my breath, as it were, and call out from the bottom of my heart, "Lord, help!" Here is the next sentence:

Only to look at some persons seemed enough to put me out of humor, and make me feel like saying cross things.

And now I think I will give you the whole of the little pamphlet.

THE LANTERN PEOPLE.

I have been thinking how strange a thing it was that I disliked so many people and liked so few.

Only to look at some persons seemed enough to put me out of humor and make me feel like saying cross things. But there were others although not nearly so many of them whom I loved to meet, and whom I could hardly be cross to if I tried. I had been thinking about this, when I fell asleep and had a dream.

I thought I was carried away to a strange country where it was always dark. No morning ever came there, the sun never shone, and there were no stars in the sky. Yet people were living there, and I could see them walking about. But they were very strange people, such as I had never seen before, nor heard of, nor even thought of. I called them the *Lantern People*, because they looked like great lanterns with lights inside of them that shone through. And they were of a very strange shape, for they had ever so many sides, and on every side was a picture. Some were pretty and some were ugly pictures. Every person I saw had both pretty and ugly sides.

Of course I was very much surprised, and stood looking a long while; for the people could not see me, though I could see them and was close to them. On some of their sides were pictures of snakes, wasps, and pigs; on other sides, of doves, lambs, flowers, and such beautiful things. And now I want to tell you a very curious thing about the way these people did when they met each other. I noticed when a man met another in the street, he would quickly turn around one of his sides, so that the man he met could see it and nothing else—that is, nothing but the picture that was on the side turned toward him.

While I stood watching I saw a man coming along, and he turned almost the whole way round, so as to bring the picture of a dog in front, where it could be most plainly seen. It was a bull-dog—one of the sort that shows its teeth, very ugly and savage-looking. I could not understand why he should take so much trouble to turn out that ugly picture (for he had prettier ones that I could see) until I saw another man coming toward him who turned out a picture uglier still. It was of a wolf.

As soon as they came close up to each other the pictures seemed to be alive. I was astonished to see their eyes move and their mouths open and

shut, seeming to snap at one another, and all I could hear were barking and growlings until they had gone, the fierce beasts, trying to bite each other as far as I could see them.

Next came a little girl. Happening to look behind her, she saw another little girl following her. At once she turned around one of her sides, that had the picture of a wasp on it; but the little girl who was coming after her turned the picture of a beautiful butterfly. As soon as they met, the wasp began to buzz and dart out its sharp sting, and I saw the butterfly fluttering and fluttering, till presently it was scared away, and the picture of a great spider came in its place. Then the spider seemed to dart at the wasp, and the wasp tried to sting the spider; and the little girls went off quarreling as fiercely as the two men had done.

Next I saw a young woman. She was prettier than any other of the Lantern People that I had seen. I saw her coming from a long way down the street, and she never turned her sides, no matter whom she met, but always kept one picture in front; and that was of a dove. It had a ring of black around its neck, and an olive-leaf in its beak. I thought to myself, "What a beautiful picture!" Just then another young woman came up and pushed rudely against her, and I saw this rude one turn out the picture of a snake. And the snake hissed and darted out its forked tongue, but the dove would not go. All it did was to coo softly and flutter its wings and hold out the olive-leaf.

When the snake found that it could not frighten the dove away, it began to creep off itself, as if ashamed; and what was my surprise to see presently another dove come in its place! And the doves began to coo to each other, and to look pleased and happy, and the two young women took hold of each other's hands; then they put their arms around one another's necks and kissed each other, and so walked happily away. And I awoke. This was the end of my dream.

My young friends, do you know what it means? It means that we may be gentle and kind to each other, or we may be cross and ill-natured, as we choose. The dogs, the wasps, and the snakes, mean ill-temper; the butterflies and the doves mean gentleness and kindness. When we do not like a person, we are very apt to turn toward him our ugly side; that is, the picture of the dog—or the snake, or the wasp. And if we do this, it is most likely he will turn his ugly side toward us. Then we quarrel and hate each other; and it is no wonder. How much better always to keep turned toward others the picture of the dove! Should we do this, it would be seldom indeed that the dove would not, sooner or later, be turned toward us.

Do you want to know who wrote it? I suppose it was our good friend Charles Foster, the author of the "Story of the Bible," and the little tract seems to be an advertisement of this book, which so many of you have read. Now then: Is it right that we should go through the world loving so few of our neighbors, and disliking so many? Jesus said, you know, "Love ye your enemies." Sometimes I think I do love even my enemies; that is, I think my greatest desire is to do them good, and that I rejoice at an opportunity of doing them a kindness; but, oh dear me! how quick I slip back and forget! Yes, I forget my Master and Savior who died for his enemies, because he loved them. Help me, O my Savior! Help me in this task that seems at times an almost hopeless one, of trying to turn nothing but a pleasant picture and pleasant exterior and a peaceful face to all my neighbors, no matter under what circumstances I find them or where they find me.

Even now as I breathe this prayer, light seems breaking over me. What a sad, sad world this would be, had the Savior never come to it! How many, many times, when troubles and trials come all around me, have I sought that refuge—"Come unto me, all ye that are weary and heavy laden." How

much is this promise worth to us! Over and over again I think of it. All that the world can furnish, all that this vast universe can give in the way of happiness, sinks into insignificance when compared with that great boon, Christ's love and his help. "I am the way, the truth, and the life."

RAISING STRAWBERRIES.

MRS. MAHALA B. CHADDOCK TELLS US HER EXPERIENCE.

IT is real interesting to watch the Editor of GLEANINGS when he gets to doing anything; he is so excited about it, and so sure that that is just the thing. I have been through one attack of the strawberry fever, and I know all about it. I had an idea once that a fortune could be made in strawberries. It is the easiest thing in the world to count up. If I sell \$100 worth of strawberries from half an acre of ground, I could sell \$200 worth from one acre; and on 80 acres I could raise \$16,000 worth, and in a few years—a very few—I should be rich. Well, the very next year I did not sell \$20.00 worth. It was a dry year, and the berries all dried up, and it ran on until we did two years with no berries for the table.

Last August, a year ago, I made up my mind to have some strawberries once more. I couldn't get any ground plowed, much less manured, subsoiled, underdrained, etc., but we had a patch of sweet corn that was to be fed to the cows, and Mr. Chaddock said I might set the plants there if I wanted to; but that as for him, he had no time to "bother" with strawberries. I engaged the plants in Vermont, five miles away, and was to go for them when the first rain fell. One night it rained all night, and the next day I went for them; but the man said it was too wet to go among the plants; that I must come again when it was not muddy. In a week I went again. This was on Saturday afternoon; and when we got home with the plants it was 6 o'clock. We must eat supper, milk the cows, and set out those 400 plants. Mr. Chaddock could not help any, because he was school director, and had to go to a meeting of the board that evening. We dug little holes with case-knives, poured half a pint of water in each hole, and set in the plants, putting them in a crooked row between the rows of corn. Jessie and Mamie Marshall (a visitor) gouged the holes; Harry carried the plants, and dropped one at each hole (sometimes two), and Minnie and I set them (Irving had to go after the cows and do the milking). Presently it grew dark, and the children grew tired and sleepy, and I sent them all to the house, and I took the lantern and finished setting the plants alone. I am a brave woman; I care nothing for robbers nor tramps: I can not imagine what the feeling is, that makes one afraid of the dark; but I was a sick woman; and when my back gave out I crawled on my hands and knees from one end of the row to the other, till the last plant was set; then I crawled to the house, and went to bed, and that night it rained, and every plant grew. Now, it seems to me that my way of setting strawberry-plants is a great deal more real than for Mr. Root to stand by a gardener and direct him to put one plant in each pot, and talk of the beauty of raising strawberries.

MAHALA B. CHADDOCK.

Vermont, Ill., April, 1885.

My friend, I know just exactly how you felt when you crawled on your hands and knees, and got the last of that big lot of plants set out, and whether the rest felt like helping any more or not. I think I know, too, how you felt when it rained and they all grew. Energy is a grand thing, especially just the kind of energy you speak of. But I think it is grander still when it is harnessed and made to work evenly, consistently, and methodically. Commence a whole year ahead, if necessary, in preparing your ground for strawberries. Underdrain it at one time, subsoil it and plow it as you know it ought to be at another time. Raise some plants yourself; and if you have them in pots, you won't need to mind very much whether it rains or not. We were setting plants out but yesterday, and the ground was so soft and nice that we did not have to gouge out holes with case-knives, and pour water into them. We stretched a stout cord the whole length of the field, clear from the carp-pond up almost to the house. Then we made the horse follow that cord, and plow and furrow in the soft dirt. The ground had been manured and harrowed and rolled and dragged, and worked up until it was so soft that almost any child might envy the job of moving the fine rich mold with his fingers. Mr. Weed says if you give him ground like that, and every thing fixed just right, he thinks he could set out 10,000 plants in a day. I know his back would ache almost as bad as yours, though. Mrs. C., by the time he had got half of the 10,000 planted; but I should feel a good deal more respect for the boy who got the back-ache that way (or girl either for that matter), than if they got the backache in a five-mile contest at the skating-rink.

A BEE-KEEPER IN TROUBLE.

ONE OF THE JUVENILES TELLS US ABOUT IT.

HERE is papa's report for last year. He says it will do to go in Blasted Hopes, if any will. Out of 80 stands of bees he never received one pound of honey, and to-day finds us with only 8 stands living. Bad luck seems to be his lot in every thing. He has not been out of the room for twelve days; he got his arm and hand caught in a belt in the elevator where he was at work, and tore it nearly all to pieces. It is his right arm, and he can't write to you. He says you will have to stop GLEANINGS, for he feels too poor to take it any longer. It frets him because he can't go to Sunday-school, but he still puts his trust in the Lord, and hopes for a better day to come. Please write to him. FRED PARSHALL.

Skidmore, Mo., April 20, 1885.

Why, Freddie, things do look dark at your house indeed, do they not? I am afraid your papa let his bees starve, did he not, or did they get aphid honey? I did not know there was much trouble in wintering so far south as you are. You say you did not get one pound of honey from 80 colonies. I believe that is one of the worst reports I ever knew. I should not have neglected to prepare them all for winter, though, even if I did not get a pound. Your locality has, in

former years, given very good results, and it will yet—never fear. Go to work, Freddie, and make the most you possibly can of those eight remaining colonies. It will not be a very difficult matter to fill the 80 hives again, in your warm climate.—Now in regard to that accident. It is true, accidents of this nature will sometimes happen, but I am afraid your pa must have taken risks. We trust the damage will not be so bad after his arm is thoroughly healed up.—No, Freddie, we are not going to stop GLEANINGS. With your papa's permission we will keep it going right along, and may be some of the brethren may feel disposed to help you fill your 80 hives, in the way of donating a queen or two, when they can spare them. The brightest part of your little letter is the winding up, where you say your father is still going to put his trust in the Lord. Tell him to remember the words, "Whom he loveth he chasteneth." Now, when things get better, Freddie, please write us another letter, will you not? There is another pleasant thought, Freddie: Even if it should please God to permit your father to be kept away from Sunday-school, the school he was instrumental in starting will still go on, and will be a blessing, who knows how long?

ANOTHER LETTER FROM JAPAN.

HOW THE JAPANESE OBSERVE NEW YEAR.

MR. ROOT:—Please excuse me for not acknowledging the book you sent me, sooner. I was quite sick at the time it arrived, and was unwell for over a month. Then Christmas time drawing near, it made me very busy.

I should like to tell you about our Japanese Christmas service, but this year we postponed it till some time this month, and so it is impossible. The Japanese make a great ado about the new year, so I will tell you about that.

Every house is cleaned so as to look bright on New Year's day. They are decorated with a lobster, which signifies "many happy returns of the day till your body bends like a lobster" (I suppose you have noticed that boiled lobsters double up). On either side of the entrance is placed a pine-tree, and two or more pieces of bamboo. Sometimes the trees are joined by a rope, to which is fastened a number of pieces of paper, which are supposed to drive away evil spirits. The above festivities for the new year seem more like men's work, but you must not think the women are idle; they have to make their own and their families' clothing, for they must (?) all be new, since every Japanese wants to have some new article of clothing.

Just before the new year, all of the shops containing kites, toys, hair-pins, and battledores, are renewed, and they sell these very cheap then; but on New Year's day the prices rise enormously. Many of the cake-shops bake large round cakes made of "mochi," or mashed rice. They are set upon a little table in the houses during the festivities, after which they are thrown away. Many cook their meals for the first three days of January beforehand, so as to have a good rest at the beginning of the year.

If you would go out on New Year's day in Japan

you would find yourself in the midst of happy faces and bright dresses. You could not go far without seeing a group of young men and women playing battledoor and shuttlecock. They always have a box of Japanese black ink, with which they paint the faces of those that miss. You would also see young men, and even old men, flying kites beside the little boys. Every one is out in his good clothing. Flags and decorations are on every side. There are many happy faces, and the little babies beside the other children usually have a piece of candy or a toy in their hand.

I must not forget to mention the Japanese custom of making New-Year's calls. They try to visit all of their friends by the 3d of January; but if that is impossible, by the 5th. Japanese call it an almost unpardonable rudeness if all of their friends have not been to their house by the 7th.

Tokio, Japan, Jan. 2, 1885.

ADA KRECKER.

HOW TO RAISE CRANBERRIES.

WRITTEN BY ONE OF OUR 15-YEAR-OLD JUVENILES.

UNCLE AMOS:—As you say you are going into the cranberry business, and want some advice how to prepare and set out a bed, I will tell you what I know about it, for my pa (L. C. Seaton) planted a bed in Minnesota, and I helped him, so I have some knowledge how it should be done.

The most important part is the selection of a site. A peat-bog, or a mucky slough, that is so situated that it can be drained or flooded at will, is a proper place.

Alluvial formation is the only one in which the cranberry can be successfully cultivated; but you want to avoid gravel, clay, and loam, as detrimental to its growth.

This end of bed is lowest, so the water will flow through the ditches.

Inlet
Drain

DIAGRAM OF CRANBERRY-BED.

This bed can be any size desired, but the drains in dry land must be only about 8 feet apart; but if the land is pretty damp they can be further apart, even 10 to 16 feet. It is best to fill in the inside of dam with sand; it will hold water better, also prevent weeds from growing on inside of dam.

If you have a peat-bog, you want to take a sharp

spade or grub-hoe and cut off the bogs or uneven places, and make it just as level as a floor. If your bog has a sufficient depth of muck to support the vines, say 16 inches deep, then the pieces cut off to level down the bed can be placed around it to help form the dam (for you will need a dam 2 feet high all around your bed to hold the water to flood your vines during winter).

Now cut a ditch about 8 inches deep and 8 inches wide on the top, and 4 inches wide on the bottom, running zigzag the whole length of your bed, as shown in the diagram.

The object of this ditch is to drain and water your beds. If your beds are made in a springy place it will drain it; but if in a dry place you can water it through these ditches. By keeping the water constantly flowing through them at a depth of 3 inches it will soak through the beds and give your cranberries the proper amount of moisture.

Now, this bed wants to be covered 3 or 4 inches deep with pure clean sand, free from foul seed; this will keep down grass, weeds, etc., and is just what the cranberries require to give them a healthy growth. If you have no peat-bog, but a slough covered with water, then drain it, level off as before, cover with sand, and you will have an everlasting bed that will grow better the longer it stands. If you have neither requisite, then you must dig a trench 12 to 16 inches deep, the size you wish your bed, and fill with muck or peat, and cover with sand as before.

When one has plenty of water at hand, a pretty good cranberry bed can be made on a bed of clear sand, but the trench through the beds must be closer together, and water kept constantly running, and thoroughly flooded from one to two feet deep through winter.

If cranberry-vines are planted in too rich soil they will all grow to vines, and not bear well; hence the necessity of sanding and flooding. The Cape Cod is the best variety to plant for general use. The vines can be planted at any time during spring, when the beds are prepared, by cutting the vines into pieces about 4 inches long, and planting in the sand, leaving the ends sticking out an inch or so. The closer together they are planted, the sooner they will mat the ground, which they must do before they become good bearers.

Some have run their vines through a straw-cutter, and sowed them like oats, and dragged them in, and had good success with them; but in a small bed the best way is to take a garden-trowel or small hoe, and strike it into the ground at an angle of 45 degrees; lift the sand up, drop 2 or 3 vines in the hill, replace the sand, press down with the foot, and the work is done.

I have already written more than I intended, yet I have said nothing about the proper time for flooding and draining off water in spring, etc.

J. D. SEATON, age 15.

Ellensburg, Kittitas Co., Wash. Ter'y.

Many thanks, my young friend. Your account is given excellently; and even though we should not go into the business, it is worth something to know how such things are done. By the way, it seems to me that that system of irrigation would produce splendid results with many other kinds of vegetation. I should think that it would be quite troublesome having so many open ditches, especially if one were going to use a

horse in working in the ground. Why would not a good-sized tile answer the same purpose? Water flows on our low land through the tile almost all the time, more or less. Last fall I visited a celery farm where they put tile just the depth they wished the water to come, and it did the business beautifully. We shall be glad to know something more about the flooding, my young friend. And we should also like to know how your father made it pay. Is he raising cranberries yet?

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows: viz.: *Sleeper Off*, *The Giant-Killer*, *The Roby Family*, *Rescued from Egypt*, and *Ten Nights in a Bar-Room*. We have also our *Homes*, Part I and our *Homes*, Part II. Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

"A chief's among yee takin' notes.
An' faith, he'll print it."

WELL, my little friends, if you were to come to see me this beautiful May day, what do you think I would have to show you? I guess it would be the new poultry yard and house. I made the yard of two rolls of poultry-netting, and put the house in the middle. Then I had it separated so I could have Plymouth Rocks in one end and Light Brahmas in the other. The Light Brahmas I like the best, as they are so gentle, and nice looking too; and then they give us such beautiful big brown eggs every day. Huber and I gather the eggs; and when they are nice and clean we have a real good time admiring each one of the eggs. The Brahma rooster is almost as tall as Huber, and Huber can put his arm around the rooster's neck, without scaring him much either. A few days ago, when the men were at work on the house they let the two roosters get together, and, oh my! how they made the feathers fly, and blood too, some. I went and put my arms around the Brahma, and led him back home, and then I began talking to him about the folly of fighting when there was not any thing to fight about at all. What do you think he did? Why, he turned around and bristled up, and was going to fight me. I laughed so hard that it probably reminded him what

he was about, and he went off looking kind o' sheepish. I think I shall have to put that little verse up somewhere along the division fence—that one that commences,—

"Let dogs delight to bark and bite."

You know the rest of it. I can not tell you to-day how the house is fixed, but may be I will have our engraver give you a picture of it. It has two porches—one on the east and one on the west side. The fowls spend most of their time in the porches.

FREDDIE'S 100 CHICKENS AND 60 EGGS A DAY, ETC.
Our bees wintered very well. We had 26 hives, and lost only one. In one hive the queen was not good, and we killed her. We are getting 60 eggs a day. We have 9 geese and 100 chickens.

FRED W. ISRAEL.

Damascus, Col. Co., O., May 4, 1885.

A LETTER FROM A MOTHERLESS LITTLE GIRL.

My mother died last October. I have one brother and one sister. Pa had 43 swarms of bees in the fall; 4 swarms died this winter. I have one swarm. When our bees get to robbing, pa exchanges hives and they go in their own. Pa sent to the U. S. Fish Commissioner for some German carp.

Constantine, Mich. EDNA RIFENBERGH, age 11.

A SWARM OF BOYS, ETC.

My papa keeps bees. He delights very much in them. We all like your ABC book and GLEANINGS. I like honey better than stings. I do not get about the bees much. Mamma needs me in the house most of the time. I have no sister, but five brothers, all younger than myself. Papa says if a man wants to be successful in bee-keeping he also needs a swarm of boys about him.

Davidsburg, Pa. CEVILLA K. EMIG, age 11.

A LETTER FROM A WEE SCOTCH LASSIE.

I am a wee Scotch lassie called Mina; went to school last harvest with sister Gina, and I am going often. Father is a great bee-keeper, and won the prize for the Highland essay. He takes his bees to the Lead Hills every year for heather honey. He is not well, and I help him all I can. When I was 3 I asked him if the wee bees and wee een to see in the dark—not the dark of the skep, but the dark when I am sleeping. A bee-freen calls me Wee Bee ever since; isn't that funny? It will be far to send me a book for this. WILLHEMINA SMITH THOMSON.

Auchinraith, Scotland.

ERNEST'S PAPA WITH HIS FOUR APIARIES.

My pa has four yards of bees; 52 colonies in one place, 40 in another, 30 in another, and 45 in another; they are in cellars, except 55, which are buried under the snow. It has been 48 degrees below zero here this winter, but the bees are doing well. Part of the bees, pa is working on shares. He has 100 sheep. It is fun to see the little lambs skip and play. Ma has 49 Plymouth Rocks that laid 248 eggs in the month of February. ERNEST A. GILL.

Viola, Wis., March 14, 1885.

Thank you, Ernest, for your report. We know your pa, and have known for some time that he was a big bee-keeper. Two hundred and forty-eight eggs in the month of February would be not quite nine eggs a day; but I should say that was tiptop for forty hens in February, away up in Wisconsin.

Grandpa had 53 swarms of bees in the fall, and now he has only 26. My papa is a Methodist preacher.

MABEL POTTER, age 7.

Worcester, Wis., April 24, 1885.

FROM ONE OF OUR FLORIDA JUVENILES.

My papa has a few hives of bees. We have 19 little chickens. We have a dog and 8 pigs. They are growing fast. We have 9 pigs, with the old one. I have a cat.

LETITIA LUTCH.

Hawks' Park, Fla., April 6, 1885.

CHARLEY'S REPORT.

Papa has had bad luck with his bees this winter, for it has been very cold here. We had a large snow here yesterday, but it is nearly all gone now. It was so cold that papa thinks that some of his bees are frozen to death. He has one hive that has lost its queen, and is nearly dead. If it dies, that will bring his number down to 69.

Windsor, N. C., March 23. CHAS. HARDEN.

SAVED 103 OUT OF 115.

We have had a bad winter. It was awful cold, but papa's bees wintered well; lost only two out of 105. The weather was warm last week; the blue-birds and robins were singing their merry songs, and the bees filled the air with their busy hum, which made us feel as if spring were here; but it has turned cold again.

CHARLIE NEBEL, age 11.

High Hill, Mo., Mar. 9, 1885.

HOW ELMOR DEFENDED HIS SISTER.

We have one swarm of bees. One day my sister and myself were watching the bees work, when one stung my sister. She had never been stung before, and it made her jump. She started to run, and ran right toward me. I tried to get out of the way, but she kept coming to me. But I got away and she went into the house.

ELMOR WILSON.

Allerton, Iowa, Mar. 6, 1885.

HONEY FROM THE PERSIMMON.

My papa has 9 hives of bees. Last year he got 250 lbs. of comb honey from six hives. The honey from the persimmon-blossom was the best of all. The bees make more honey from the persimmon than from any other source. The bees work on it from morning till night. We use the Langstroth hive with pound sections. I love to help take honey. I am not afraid of the bees.

LINDEN K. SHEPHERD, age 9.

Kent's Store, Fluvanna Co., Va., Feb. 26, 1885.

TWO QUEENS IN A HIVE.

We have six colonies. Mamma sold two for hives. I have two colonies of bees. One has got four queen-cells. I went to look at my other one, and a bee stung me just below my eye, and it hurt so badly that I could not see. I do not get stung often; but when they do sting me it hurts; you ought to have seen my face. Have you ever heard of two queens living together? We had such a case last fall. They kept building queen-cells, and we divided them twice, and after that we looked in and found a young queen, and we let her stay; and this spring, when we looked in, the old one was gone.

LIZZIE WITTE.

McGregor, McLennan Co., Texas, Apr. 22, 1885.

Yes, Lizzie, it is quite common to find two queens in a hive, under the circumstances you mention—an old one and a young one, mother and daughter. The A B C book will tell you all about it.

ONE LEFT OUT OF THREE.

My papa has one stand of bees; he had three last fall, but two died. We have not had any honey from them yet. Papa never wears his veil when he is hunting for the queen; he is not afraid of them.

LENA W. BRIGGS, age 11.

Eddyville, Mass., Feb. 6, 1885.

A SHORT LETTER ABOUT MISTAKES.

It is a mistake to put off feeding until the nights become cold. Better be too early than too late. It is a mistake to use up all the pots, kettles, pans, spoons, stove-hooks, and other things upon which to play the dead-march, when a swarm has started on an excursion to the groves.

B. B. GILLET.

Allerton, Wayne Co., Ia., April 9, 1885.

FROM 4 TO 7, AND 500 LBS. OF HONEY.

My pa has 15 colonies of bees. He looked at them the other day, and found two of them dead. He had 7 swarms of bees from four colonies. We got 500 lbs. of box honey. We winter them on their summer stands. We pack them in chaff hives.

JOHNNY CARTRIGHT.

Weltonville, N. Y., April 12, 1885.

MARKING HIVES.

I am a little orphan-girl, and live with my married brother. We all love to read GLEANINGS, and work with the bees. You say in A B C, when the hives are close together there should be some mark on their homes so they would not get lost. To help the little bees, my brother has their hives all in a row, and nicely painted, one blue and the next one white, so on all through. I love their blue-eyed baby-boy. He calls his little wagon "hut O."

LILLIE CURRENS, age 12.

Goodland, Ind., March 12, 1885.

TAKING THE BEES OUT OF THE CELLAR.

It is pretty warm here to-day, but there is a lot of snow. We carried out 8 swarms; they had a good fly but it is rather cold yet. My pa was looking at a strong swarm, and he found a young Italian drone. Is it not early for them in this cold country? In looking over the bees in the clamp, pa found one dead with dysentery since my last; that leaves us 3 dead out of 30, up to date. There are small parts of the fall wheat bare, and it looks very well. When I received the big envelope to-day I opened it, expecting to get a price list; but, lo and behold! to my surprise I found the beautiful book, Pilgrim's Progress. I do not know how to express my thanks.

Shelburne, Can.

CHARLES E. THOMPSON.

LITTLE ZOO'S LETTER.

I is rich now. Tozzer boy say, "How is oo rich?" I has the doodest light when the sun dets up, de puttliest dreen grass and fowers, and the dew-drops shine on 'em like the diamonds in your ma's rings; den after while the nice berries come on 'em; we tan eat 'em or dry 'em, tin have 'em on the table and in our pay-house. We fins dem up and down the nice roads along dem pretty fences and the banks of the creek, and blances; den the pretty birds sing for us while we gather them, and we gets dood tool water to drink. When the pretty light goes out over the hills, the pretty stars peep out and shine right on me, an I spec my eyes shine right at 'em too. Tozzer boy says 'em aint mine, but ma says da is; that the dood man gims 'em to me, and all of us. So I feels rich with all these dood and pretty things, des waitin' for me to tall 'em mine.

Zoo.

FROM A YOUNG BOATMAN.

My pa keeps bees. He had 50 stands in the fall; but the winter has been so cold that I do not know how many we have now. We did not get very much honey last fall. We take GLEANINGS. I learn a great deal by reading it. We live on the Des Moines River. My pa is ferryman. I am a little boy, but I can row a boat. Come over and I will give you a boat-ride.

ELDIE WALKER.

Rousseau, Iowa, Feb. 7, 1885.

SUSIE'S LETTER.

Pa commenced with 16 stands of bees last spring, and increased to 60, and extracted 1400 lbs. of honey, and I turned the extractor. All of the bees died but 41 stands, and they came out all right this spring, and those that died had plenty of honey in the hives. I should like to know the cause of it. Last summer I had to let pa know when they swarmed. We hope to have a good honey crop this year.

SUSIE GARRISON, age 11.

Whitehall, Ill., April 25, 1885.

THE FIRST SWARM OF BEES FOR 1885.

A swarm of bees alighted on a fence at one of our neighbor's, and they found them and put them in a hive that had comb and honey in it, and he says they are doing well. It was on the first day of April. They must have come from the woods. There was about a quart of them, and they had a queen. My papa has six swarms of bees in chaff hives; he lost none this winter; my grandpa lost a good many of his bees, and so have our neighbors.

Dayton, Ohio, April 15, 1885. VIOLA TURNER.

AN ORPHAN BOY'S LETTER.

I am a little boy of 13. I work in the field every day. We have a great many hives of bees, and get a great deal of honey. We sell it by the gallon. We eat a great deal of it on the table. It is very good in cold weather. I have a large truck wagon, and I work yearlings to it. I am an orphan boy, but I have a good guardian. I have been with him six years. I have a little single-barrel shot-gun. It throws shot 100 yards. I can kill a bird flying, or any way.

T. S. TRAVILLIAN.

Caseyville, Miss., Apr. 8, 1885.

FIVE CENTS A SWARM.

My papa keeps bees. I watch them, and when I see them swarm I get 5 cts. One day last summer a swarm came out, and we just got them hived when a wind storm came up. It blew the hive over, and we lost a good many bees, and lost the queen. A neighbor was helping papa hive the bees, and the bees alighted all over him, and stung him so badly that he did not sleep any that night, and he said he would rather eat the honey than to hive the bees. I am a left-handed girl.

ANNIE BENNETT.

Alexandria, Minn., March, 1885.

HOW MINNA LOST THE BEES BECAUSE SHE FORGOT AND LEFT THE COVER OF THE HIVE OFF.

I had a swarm of bees, and moved them 13 miles, and they did well for about a week. They commenced coming out, and I went out to look at them and left the top of the hive off, and next morning they were all dead. I was very sorry, for I loved to tend them. Grandma and myself went on shares, and she had 36 swarms and lost all but 4, and I lost mine too, but I am going to get me another one.

MINNA DICKENS, age 14.

Mossing Ford, Va., April 19, 1885.

ABOUT STRAWBERRIES.

I don't like honey, but I like strawberries. Papa has a nice bed of Parry, Sharpless, and Crescent Seedling strawberries. He thinks the best way to raise them is to set out a new bed every spring, and dig or plow up the old ones as soon as they are done bearing.

HARRY I. DOW, age 6.

Corning, Steuben Co., N. Y.

THE DEAD QUEENS.

We have six hives of bees. One colony carried out a great many dead bees and three dead queens one day last month, and laid them on the alighting-board, and they have one live queen and a great many bees yet. Father picked up the dead queens and put them in a glass tumbler. He says the young queen stung her mother and sisters, and killed them. One other colony carried out their queens, and father bought a queen and gave them.

NONA JOHNSTON, age 8.

Brock, Neb., April 7, 1885.

HOW JOSEPH'S FATHER GOT A START IN BEE-KEEPING.

My father takes GLEANINGS, and thinks it is very interesting. He has 15 colonies of bees, but they did not make much honey last year. You can not guess how pa got some of his bees. He was out hunting two years ago last January, and he found them in the top of a big tree, hanging under a limb, and he shot them off with his rifle, and then piled up the comb and went home and got a bucket, and brought them home and put them in a hive.

JOSEPH H. THARP, age 10.

Harmony, Fredell Co., N. C., March, 1885.

ANOTHER LETTER FROM DAISY WHITE.

My pa keeps bees; he has 162 swarms at home, and 45 swarms away from home. It has been so cold for four weeks that pa doesn't know whether any swarms have died or not. We have got an acre of strawberries. I suppose we shall be very busy next summer, picking them. I have a baby-brother, and he can sing ever so many tunes. He is not two years old yet. He enjoys riding on the little sled as well as Huber. He likes to see us skate. I should like to go out to Medina again. I had such a nice time when I was there. I enjoy reading the letters in GLEANINGS.

New London, O.

DAISY WHITE.

CHARLEY'S POETRY, ETC.

Bad luck with my bees this week. I had only two hives; one of them was in the woods. Father went to it yesterday, and the nemic had killed the bees and eaten the honey, so that leaves me only one hive, but I hope they will swarm this spring.

THE BEES.

Up they are, bright and early,
For they love the sun-land dearly
You see them flying all the day
Hard at work and never at play
Often, after dark has come,
You see them flying for their home,
When at their hives they buzz their wings
They never tire, poor little things!
But, oh the little things
In battle use their fearful stings,
But, hush! then you certainly must
Or not one of them can you trust
But when the cold winter comes,
And shuts them in their homes,
By cold they'll all be slain,
If they come out too soon again.

CHARLES T. HARDEN, JR.

Windsor, N. C., April 6, 1885.

LETTER FROM A CALIFORNIA JUVENILE.

Our bees swarmed and alighted on the fancy woodwork of our cupola, or tower; my brother is

the bee-keeper, and he was not at home. My father and a gentleman living with us got through a trap-door in the roof and bived them, and left them there until brother came home; then they brought them down. April 7, papa told us to come out to the corral before we had even had breakfast. We were very much pleased to see a nice little brown foal standing by our mare's side. Our papa lets her out on the grass every morning, and we go with him and run with our little foal, and we have much fun with her. LILLIAN T. HINDE, age 13.
Anaheim, Cal., Apr. 9, 1885.

ALTA'S LETTER JUST AS SHE WROTE IT.

DEAR MR ROOT. MY MA FOND A SWARM OF BEES ON AN OAK TREE. SHE PUT THEM IN THE SELLER. BUT THEY ALL DIED SHE WANTS TO GET SOME MORE. IF THIS IS WORTH A BOOK SEND THE JILLY KILLER. I AM 8 YEARS OLD.
Hatches Mills, Ind. ALTA M. COSTELLO.

WANTS A BOOK, EVEN IF SHE IS LITTLE.

If I am little and can't write, I want a book, so I get Jimmie to write for me. Jimmie goes to school all the time. I get awful lonesome.

BERTHA E. HOWE.

HOW JIMMIE'S FATHER FEEDS BEES.

As pa keeps bees and takes GLEANINGS, I thought I would write and tell you how he feeds his bees. He has a Simplicity feeder, which he sets on top or near the cluster; then with a box with a hole in the top he covers it up. The hole is covered with wire cloth; he places a tin tube through the chaff, so he can pour the syrup in the feeder. Pa got his first bees in the woods in a tree. That was in the spring of 1882; that summer he found another tree, but they had no queen, so he sent and got a queen of you, then bought one stand, so he had 3 stands to commence with in 1883. They increased to 15, and last summer they increased to 23; but pa doubled them up to 16, and now he has but seven stands left, as the chaff did not keep them from freezing. This is the first letter I ever wrote. I have one little blue-eyed sister, 4 years old. Her name is Bertha. JIMMIE R. HOWE, age 8.

Sulphur Hill, Ind., March 5, 1885.

ORANGE-BLOSSOMS FROM AWAY DOWN IN FLORIDA.

I received the book that you sent to me, and I like it very much indeed, especially the little book with little Bopeep in. We have a school now. I like the teacher very much indeed, and I like to go to school, and I hope that it will keep more than three months. Sometimes I whisper, and she keeps me in at recess; but I don't care for that, because I can have some fun. Every Friday we speak pieces. I like to speak. Tell me the name of your little girl. I have read some letters in GLEANINGS, and I found the name of Blue Eyes. I thought that I would send you some orange-blossoms. EVA GLAWSON.

New Smyrna, Fla., March 8, 1885.

Thank you, Eva, for the orange-blossoms. I am glad to know that you like to speak pieces at school. I am glad that your teacher is trying to have you stop whispering. Our little girl's name is Carrie, but we call her Caddie for short. She brings me some of her figure-work which she does at school, every few days; and, by the way, she is getting so she writes very well. I think we shall have to have one of her letters in GLEANINGS.

WHY KITTIE'S PAPA LOST NEARLY ONE-THIRD OF HIS BEES.

I got a pair of ear-rings for a present, and a nice chromo. Pa took his bees out two days ago. He lost nearly one-third. He set them in rows, packed with chaff. He was very busy last fall building a house and cistern, and neglected them. He made a brick filter in the cistern, something like that one in GLEANINGS. I should like to see little Huber. I wish you could see our blue-eyed baby. Her name is Pearle.

KITTIE M. BAIGAR.

Border Plains, Iowa, March 28, 1885.

JOHN'S REPORT.

From three colonies last spring we have taken 110 lbs. of extracted and 50 lbs. of comb honey, making in all 160 lbs., mostly from Spanish needle. Basswood yielded nothing, and white clover yielded only a small amount of honey. We increased them to 5. They are all in good condition. I packed 4 on their summer stands, and put one in the cellar. I carried it out of the cellar on the 5th ult., to give them a cleansing flight. As the bees are gathering pollen now, I think I have wintered well. Most of the farmers around here have lost a good many of their bees. The coldest weather here this winter was 26 degrees below zero. Pa is moving about 50 stands of his bees to a place called Bear Creek, five miles south of here. He has taken 30 down, and will take the rest in a week or two. JOHN V. NEBEL.

High Hill, Mo., April 1, 1885.

WHAT IS HONEY-DEW?

We received the hives all right, I am glad to say. I am a boy 14 years old, and live on a farm near Princeton. My papa keeps bees, but is traveling for the Trenton Iron Co. I put all of papa's hives together. We had 10 hives last fall, and have 8 out of 10 now. My mamma and I will have to take care of the bees this summer. Will you please tell me what honey-dew is? IRVING D. BANKS.

Princeton, N. J., April 20, 1885.

Friend Irving, it is a hard thing to answer; but I suppose the most of it is an exudation from certain insects that feed on the bark and foliage of different trees. At other times, the plants themselves seem to exude a sort of honey, or saccharine substance. For the last few days our bees have been very busy on the heads of lettuce in our cold frames. I suppose they find something that is sweet, of course, for they search every leaf carefully, and dive away down into the heads. They are on hand every morning, just as soon as the sun is up enough so they can fly.

MUSKRATS EATING THROUGH CARP-PONDS.

The animal that made the hole in your dam was probably a muskrat. They are sometimes very troublesome. My neighbor had a good dam spoiled, and all the water let out by them. He has rebuilt the dam, and stocked the pond with carp. He now keeps the rats away by watching for them, and shooting them whenever he sees any of their work. A good way is to trap them with a steel trap set under the water in their runs. J. H. TINKER.

Olathe, Kansas.

Yes, friend T., I know it was a muskrat, for one day when I was down by the creek I saw him walk along leisurely, sometimes under water and sometimes out. Once in a

while, when he found a water-plant to suit him he pulled it up and then sat down in the water to nibble it while he held the root in his paws. He looked as cute as could be, and I felt bad to mar his enjoyment. But I concluded it must be done, so I hunted up a nice smooth stone, and drew back, thinking I could pop him right square on the head, sure; but just then my foot hit a brush and made a noise. He stopped his lunch, looked at me just about a second rather curiously, and then went keeling head over heels down into the water, and finally crawled up under the turf right opposite the carp-pond. You see, he digs back in the bank there and comes out right inside of the pond, and away goes the water. He has not done it very lately, however, for we have pounded in so many tin scraps that he will spoil his teeth if he gets through again.

A PIECE ABOUT BEES—TAKEN FROM THE THIRD READER.

I will write you a piece about bees. I got it out of my Third Reader. When bees enter a new hive it is said that they divide themselves into four companies, one of which goes out to the fields in search of materials; another employs itself in laying the bottom and wall of the cells; a third in making the inside smooth from the corners, and the fourth in bringing food for the rest; but they are not always doing the same thing. They often exchange their tasks—those that have been in the fields coming in to work, and those that have been confined to the hive take their flight. They have a language, or signs, by which they understand each other. When one that is hungry meets a loaded bee, they stop, and the one that has honey bends down its trunk and lets the contents fall into the mouth of the other. Their diligence and labor are so great that in one day's time they are able to make cells in sufficient number to contain 3000 bees. Some of the bees are busy all the time in stopping the holes and openings, for it is necessary that they should be warm. Their cells they strengthen all round by bands or strings of wax, and when this is done they go over them all again with their teeth and pare away all that is unnecessary, and shape round the partitions, taking away all the chips or fragments of wax, and carrying them out of the hive. They are very neat, and keep their house perfectly clean.

ANNIE LEUCK, age 13.

Campo Seco, Cal., March, 1885.

Friend Annie, your story is in the main pretty accurate, although I think it is a mistake about bees dividing themselves into four companies, although it is true that they apportion the work among them, some working at one thing and some at another; but they exchange places so much that it is pretty hard to lay down any rules in regard to their division of labor.

HOW HARRY GOT INTO TROUBLE.

Last summer I went out to the cornfield where my father was plowing, to tell him that the bees were swarming, and that I would plow till he hived them. I got myself into trouble, and had to plow all summer.

HARRY NEFF.

Clive, Iowa, Feb. 8, 1885.

Now, Harry, I do not pity you a bit. For my part I can not think of any thing in this whole world that would be better fun than

to plow. May be I would get tired of it, but you see it is doing something outdoors, right under God's blue sky, and then it is something useful too; and even though you do get very tired, how one does enjoy his dinner after such kind of work! and then that feeling of peace and happiness after you get through at night, and have your team all nicely cared for and put away! A boy who can do a good job of plowing need never be afraid of losing his situation; and if banks break, and money is hard to get, and all these other things happen, what does he care? I can very well remember when I used to hate plowing; but for all that, I can not understand now why I ever was so foolish.

ONLY 8 LOST OUT OF 147, AND THAT IN CANADA.

We have twins. We call them Wiman and May. They are four months old. Father had 147 colonies of bees; 8 of them died. They were out of doors. Those in the cellar are doing well. Father gave me 2 colonies. They are both alive. I do chores, and harness the horse for father. I had my leg broken when I was 6 years old, and have not been able to go to school much.

SPENCER ORVIS, age 9.

Whitby, Ont., March 23, 1885.

Very good, Spencer. With 147 colonies of bees, 100 bushels of alsike clover, and twins four months old, it seems to me your father ought to be a happy man. See p. 280.

AND HERE IS A LETTER FROM 4½-YEAR-OLD BERTHA.

I am 4½ years old. I rock the babies for mother, and play with Lily. She learns not to tear books when she has them. Does Huber have books to play with? Lily tries to help me clear the table. Does Huber try to work any?

Whitby, Ont., Can. BERTHA ORVIS, per mother.

Thank you, Bertha. If you were at our house, you would think Huber did have books to play with. When I go home nights and get my *Ohio Farmer* he climbs up on my knee and begins, "Pic'er-book, pic'er-book, papa." And then when I ask him what "pic'er-book" he wants he will reply, "Want burny man;" and if I do not get it right off he will keep saying, "Burny man, papa, burny man." He means by this that he wants one of the old readers that has a picture in it of a man carrying a child out of a burning building. He can find the book anywhere in the secretary, just by seeing the back of it, when there are hundreds of other books almost like it. Yes, Huber tries to work. I do not know that he ever accomplishes very much, but I do know this: That every few minutes he makes a great heap of work, as they say down South. Well, Bertha, I think you do pretty well if you manage to rock both of those twin babies, and only 4½ years old.

COVERING BEES WITH HEMLOCK BOUGHS, ETC., FOR WINTER.

My papa keeps bees. Last year he had 4 swarms, spring count; they swarmed so we had 12 that year. In 1883 we got 179 lbs. of comb honey, and 90 lbs. of extracted. They all wintered but two. He wintered them out of doors, just as they stand in the summer. Our bees did not swarm at all last year, and we got only 100 lbs. of honey, and that was all clover, as basswood did not blossom. In the fall, papa

bought and took on shares 14 more, so he has got 26 stands now. He thinks a great deal of bees. In fact, we all do. Mamma sometimes hives them.

One of our neighbors has at two different times lost all of his bees by covering them with hemlock boughs. One year he lost 7, and another 20. The man who kept them thought that that did not have any thing to do with it, but my papa thought that was what killed them. What do you think?

BLANCH BULKLEY, age 13.

New Woodstock, N. Y., March 1, 1885.

I do not think the hemlock boughs did the bees any harm, friend Blanch, unless it was because they kept the sun from shining on the hives. Of course, it would keep off the wind some; but what we want to do is to keep away all the wind and at the same time let the hives have all the sunshine they can get.

ROY'S ENCOURAGING REPORT.

Pa began keeping bees when I was a year old. He and uncle Ned saw a swarm of bees flying over their heads in haying-time. They stopped them and put them in a hive. In a few days he bought three swarms in box hives for \$21. That fall he bought 10 swarms in frame hives for \$100. The next spring he bought a honey-extractor, uncapping-knife, and 10 lbs. of foundation of you. During the summer he made enough money from his bees to replace all the money he paid out for his bees, extractor, knife, foundation, lumber, etc., that he used. He has always made his own hives, crates, and sections; and for the last 7 years, foundation. He has never advertised, but he has lots of customers from far and near. He runs his machine with a horse power. He made a rigging to sandpaper sections, that cost 25 cents. It sandpapers them as they are sawed, and saws them ever so nice. Pa has taken your journal ever since he kept bees. He has always made bee-keeping pay. He had 75 swarms last spring; sold some in the fall, and had 99 left to winter. He got over 6000 lbs. of honey; sold 413 lbs. comb honey to one firm in Charlotte.

Chester, Mich. Roy B. HUBBARD, age 10.

Well done, Roy; but it seems to me that machine that sandpapers the sections just as they come from the saw, and costs only 25 cents, needs a little more explanation. Can't you or your pa explain a little more, for the benefit of the brethren?

SEVEN-YEAR-OLD CHARLIE TELLS US HOW TO HARNESS THE HORSES WHEN THE BEES ARE CROSS.

My mamma has told me about you, and how kind you are to little boys. I should like to see the wheelbarrow full of books you have for little boys. My mamma works ever so busy amongst the bees, but they are eight miles from home, so we have to leave some one at home to take care of things when we work with the bees, for mamma says I must find the queens for her, as I have such sharp eyes.

I want to tell you how to harness horses when bees are cross. Get get the smoker ready, put the harness on the horses, and take them to the wagon. Let one go along with the smoker, and walk around the horses, puffing the smoker, and the bees will all fly away. That is the way we do, and it works first rate. I learn my lessons and recite to my mamma. I read the *Youth's Companion*, add, subtract, multiply, and divide, without a book, and I am learning

the 16's in multiplication. I write, and study geography. I have done all this to-day, and helped irrigate, and the water drove a gopher out, and I killed it; and then Gipsy, my dog, ate it. We have a carp-pond, but they are all big, as the water is too cold for the spawn to hatch. CHARLIE WILSON, age 7.

San Bernardino, Cal., Apr. 2, 1885.

ESTHER'S STRAWBERRY LETTER.

My ma takes GLEANINGS, and we are pleased with it and the ever-welcome Home Papers. You wanted all that loved to cultivate or grow strawberries to inform you of their mode of cultivation and success. Here is our way: Set out in April or August; mulch in October so thick you can't see the ground by walking over them; this keeps them with green leaves all winter; the ground will not thaw out until it will stay so, and frost or light freezes do not reach them in the spring. Our patch of 12 by 16 feet did not do quite as well as some I saw in the newspaper, which gave from 80 to 120 quarts to the rod; but we got 32 quarts, besides some that were not measured. We took some to the festival, and sold them, three for a nickel. The largest one we measured was $7\frac{1}{4}$ inches in circumference; the most on one stem was 17 large berries.

ESTHER A. FREDLY, age 12.

Silver City, Iowa, April 20, 1885.

STRENGTHENING WEAK COLONIES BY THE PURCHASE OF BEES BY THE POUND.

My pa bought one stand of black bees, the summer before last. They have swarmed twice. The last swarm came out on the first day of July, and we were all away at a picnic. It was the eighth day after the first swarm. We expected it would come out, but we did not like to miss the picnic. But, however, when we came home, after looking around a while pa saw a ball of bees the size of a quart dipper. There was a heavy storm of rain that day, so they got under a board for shelter. About the last of August, pa was examining the first swarm, and he found that they had neither eggs nor brood, so we wanted to know from Mr. W., who was accustomed to bees, what was best to do. He advised us to get a few bees and a queen. Pa got $2\frac{1}{2}$ lbs. of Italians and a queen. At night we smoked the black bees down, and then put the Italians in. But in the morning, when we went out, we saw all the black bees scattered about on the ground. Please let us know if it was right to put so many Italians with the blacks. Pa has no smoker; but when he examines the bees he blows some tobacco smoke into the hive. People say it injures the bees.

CHAS. HAMILTON, age 12.

Apto, Ont., April 14, 1885.

Friend Charles, your father did all right, only that he did not watch the bees long enough to see that they united peaceably. He should have remained near the hive; and as soon as the first black bee came out stung, they should have had a good vigorous smoking. It is never safe to neglect this. You might have lost your $2\frac{1}{2}$ lbs. of Italians. I am afraid now that they are queenless. I do not think that tobacco smoke injures the bees; but, Charley, I am quite sure that it does injure the man who blows it on the bees. Suppose you tell your pa that we will furnish him a bee-smoker if he will give up the use of tobacco, and give us the usual promise.

OUR HOMES.

Hast thou entered into the springs of the sea? or hast thou walked in the search of the depth.—Job 38:16.

WHEN we had got into the cave perhaps a quarter of a mile, the guide pointed with his cane to the tracks of oxen, made by the saltpeter workers more than sixty years ago. I stooped down with my knife to cut one of the footprints, to see whether it had really turned to stone, as it looked to be. Our good friend Matt objected, however, remarking that, if every visitor were allowed to do that, the cave would soon be all whittled up. Pretty soon we had good evidence of the wisdom of his restrictions, for the ceiling to the cave, where it came down so as to be within reach overhead, was literally covered with names, dates, and inscriptions; in fact, it reminded one of a country schoolhouse with its carvings and markings. The guide remarked that this work was all done a great many years ago, and that for some time nothing of the kind has been allowed. I noticed one inscription something like this: "John Jones, 1815." It was made by holding a lamp so near the white ceiling as to blacken it with the smoke, and rude letters were made in this way. Think of smoking up these beautiful white ceilings, just to let people know that John Jones passed through here! I am glad this work has been stopped; and as I shut my knife, and put it back into my pocket, I concluded we must all live and learn. Further back in the newer explorations, the eye is not pained by such uncouth lettering.

Now we come to the stalactites. Some of them are old and hard, and look as though they had stood for centuries. Others are damp, and a drop of water hangs on the lower end, slowly evaporating, and adding to the length little by little, much in the way that an icicle increases in size and length as the water runs off from the roof from the melting snows on a wintry day. You can tell by the taste of this water as it trickles down, that it is charged with rocky matter in solution. Some of it tastes strongly of alum. When the water drops slowly on to the floor below, it evaporates by the currents of air through the cave, and thus piles up. By and by these stalagmites and stalactites meet and form great pillars, a view of which I give you in the cut above.

The trickling of the water has, during the ages, formed these immense supports, as they seem to be. This mammoth dome,

which is the largest of all the domes yet discovered in the Mammoth Cave, is about 400 feet long, and 150 feet in length. The height varies from 80 to 250 feet. At the left of the picture we have a view of what looks like cliffs. Some of the visitors have climbed up part way of the cliff by means of a ladder. In one place these cliffs look so much like cliffs on the landscape that they have been named "Kentucky Cliffs."

A little further along we found a place where, back among the shelving in these cliffs, little partitions have been left so as to form veritable pigeon-holes, as if some giant had had them made to tuck away his papers. Some of the pigeon-holes, when reached by a ladder, would make a very commodious room for a moderate-sized family.

And now we come to the Methodist Church. I always liked churches (that is,

MAMMOTH DOME AND CORINTHIAN PILLARS.

of late years); and when our guide pointed to us the pulpit, and indicated that the logs placed conveniently around before it were the seats used by a band of worshipers fifty or sixty years ago it gave me a thrill of pleasure to think that our early fathers worshipped and revered the same God that we do now. Services have been at different times since held in this same old Methodist Church, as I have been told. The log seats are in a state of perfect preservation, and look now just as they did when first put there, only somewhat discolored by age. From the absence of schoolhouses and churches in the country around Mammoth Cave, I am afraid that the present age is hardly keeping up the devotional spirit of fifty years ago when they had meetings here regularly.

About 150 yards beyond the Methodist Church, the guide pointed to us ruts cut in the soft mud made by the cart-wheels from the saltpeter works of 1812. This mud has now become a sort of hard stone, probably on account of the minerals held in solution by the water that helped to make the mud. And now we come to the eight huge vats where those old saltpeter works were managed, as I told you about last month. It has been suggested, that, if other sources failed, the Mammoth Cave would at any time furnish enough saltpeter to supply the world. Below we give a cut of these vats.

Before us are some huge rocks that at some time or other have fallen from the ceiling; in fact, when Matt burns one of the Bengal lights so as to light up the ceiling, you can see just where a great rock broke off. What is to hinder more of them from dropping off and burying up our little party?

GOthic GALLERIES AND OLD SALT-VATS.

Our guide tells us of a Scotchman who got so far, and, fearing that some rocks would tumble down, stopped and refused to go any further. Shall I tell you why there is no danger of their falling now, friends? It is because the rock is hard and firm, compared with what it was at the time these convulsions happened. The greater part of the Mammoth Cave is now dry and hard and firm.

By this time, one of our number whom Ernest informed me was a fellow-student in the college (but one with whom he was but little acquainted), uttered an oath. It fairly startled me. How could any one, in *such a place*, take the name of the great God in vain? A little further on, this same young man uttered an indecent remark. The eleven who composed our little band were men from different parts of the world, and from different avocations in life; but I was pleas-

ed to note that not one of them took any notice of his remark, even so much as to smile. Is it true, that blasphemy and impurity are always linked together?

Somebody sang out pretty soon, that he was thirsty. "All right," said the guide; "I was expecting somebody would be making that remark just about this time. We will go over to Wandering Willie's Spring, and get a drink."

Did I tell you that blind people are greatly pleased with Mammoth Cave? Singular, is it not? Well, Wandering Willie was a blind boy. He visited Mammoth Cave, and enjoyed himself hugely. Finally he was missing. After a little search they found him near a beautiful trickling spring. His sharp ear had caught the sound of dropping water, and the spring has been named after him. The water falls from the ceiling of a little cavern into a beautiful little round stone basin, and then trickles away through a little channel worn in the stone. A tin dipper hung from a nail in the ceiling; and while we stood around the spring, the guide passed the water, much as they used to do when we were children in the old schoolhouse, back among the woods. The water has a pleasant mineral taste to it. Here we are at the Giant's Coffin. We give a picture of it, but I do not think it is a very good one, on next page.

This coffin is 40 feet long, 20 feet wide, and 8 feet or more deep. Said I, after contemplating it a while, "Friend Matt, is there a little hole in the wall at the back side of that coffin?"

"Yes," said Matt, "there is."

"Well, that is the hole we want to crawl into."

But Matt replied that we could not crawl into that hole until he got ready, and we were going somewhere else first. The lady at the hotel had told us that we must be sure to ask to go back through that narrow passage; but as we had the promise of taking it in afterward, I was contented. A little further on we came to a ceiling almost as white and beautiful as a whitewashed wall; and, strange to tell, standing out in relief on this wall were strange figures of black oxide of manganese. The artist has attempted to show you one called the Ant-Eater. The Ant-Eater is, however, a great deal longer than is shown in the cut, and it needs a guide to explain what it is, or you might not understand it. A little further on you come to Barnum's Fat Girl, pictured on the ceiling by this same wonderful process from nature's laboratory. Still further, the Giant and Giantess. The giantess sits on the floor, looking up at her liege lord who stands over her, and for pastime they are tossing the baby back and forth.

The guide now announced that we would go back and take in that hole in the wall

behind the Giant's Coffin. Well, I tell you it is a hole. It is low and narrow. We had to almost get down and squeeze in; and if I were exploring it myself I should say, "Why, this surely can not be any thing; let us go back." Presently, however, when most of us began to get red in the face and feel cross, the ceiling began gradually to "let up" somewhat. Finally, we drew a breath of relief when we could stand up and throw back our shoulders. Pretty soon we came to large rooms, until it was fully as large as the main Mammoth Cave. It seems funny that every little hole one sees, if he can manage to squeeze into should soon begin to open out and enlarge, and finally open up into large domes and caverns, and great beauties.

Here we come to a lot of monuments. They are made of loose stones put up pyramid fashion. Some of them were stuck full of cards and papers, and they bristle like feathers from a sitting hen when you want to count her eggs, for instance, to see if they are all there. We looked to the guide for an explanation. "Why, boys, you see the managers of the cave have shut down on people writing their names all over; but to satisfy the craving for leaving a record of your visit, they allow visitors to stick their cards in these monuments. There is a monument for each State, as you see. There is Ohio. You, my friend, are to pick up a stone and put it there, with the monument of your State; and you Pennsylvania man can put one there." We did as we were ordered, and the guide told us that these monuments were made by each visitor placing a stone; so you see I helped to build a monument to the memory of the State of Ohio.

Halloo! here is a village. Nine stone houses in regular order, built of hewn stone, and all perfect in every respect, except that they are roofless. We stop and look at the guide inquiringly; and while he tells us that a lot of poor consumptive brothers and sisters lived here five months in these stone houses, without once seeing the light of day, we stand around him with open mouths, in astonishment. They were wealthy people from Cincinnati; and, like consumptives when pretty near their last days, they were continually catching colds; and before they could recover from one they would catch another, and somebody suggested that, as the temperature here is even and regular, and as there are no drafts of cold air, they might possibly extend their period of life a little longer, even if recovery were impossible. The exhilarating air, too, that enabled us to walk so many miles without thinking of fatigue (see p. 284, April 15), it was thought, might be a benefit to these poor sufferers.

"Well, how did it turn out?" we asked.

"Well," said our guide, and we thought a

little sadly, "they did not get any better, and the project of a sanitarium in Mammoth Cave was given up."

One of the poor sufferers died in the cave; and his friends thought he died sooner than he would have done had he been outdoors. They suffered for want of sunshine, just as one might have supposed they would, and just as the plants suffered in the little gardens adjoining these stone houses, where they tried to have a garden. If somebody could let the sunshine down through by means of some enormous sashes (like the crystal palace for instance), and then have the air of Mammoth Cave, with the other appurtenances, it seems to me the project might be a success after all. If it would not cure consumptives, may be it would help us to winter bees, and that is the point that is dear to our hearts, many of us, just now.

We now enter one of the most beautiful

THE GIANT'S COFFIN.

features of Mammoth Cave. It is what is called the Starry Chamber. The walls widen out and rise up in precipitous cliffs, so high that the ceiling is lost in darkness. A bench stands against one of these abrupt cliffs, and the guide remarks that perhaps we would like to sit down and take a little rest. Then he extends his hand for our lanterns, and we look at him a little curiously as we hand them over. Finally he has the whole eleven dangling in his two hands, and down he goes amid the loose rocks into a low remote corner of the cavern. Pretty soon he is lost to view, and all at once a sort of awe begins to steal over us as the dense darkness begins to penetrate our very bones. Dark? Why, it is literally the blackness of darkness. One begins to feel a little queer as time passes; and as Matt does not come back, some murmurs begin to arise. The friend before mentioned utters an oath; but it strikes me again, that, of all places in this world, this is the wrong

place to swear. Finally somebody utters an exclamation of surprise, and calls us to look up. Wonder of wonders! There are the stars twinkling down upon us from the vault overhead. Yes, and there is a comet, and anon some fleecy clouds appear, illumined by the rising sun. Oh yes! this is the Starry Chamber, and the light that looks so irresistibly like a gray tint of dawn is caused only by some Bengal lights the guide is burning. As we listen we can hear them hiss, and finally he comes dangling his lanterns, and laughing at the trick he has played upon us. The ceiling of this Starry Chamber is as black as black marble; and spotted all over its inky surface are little crystalline spots of crystallized gypsum; and as the light strikes them this makes the stars.

A little further, and a great log of wood sticks down from the ceiling. Who put it there? How did it get there in Mammoth Cave, any way? and who stuck it through that great rock? The water did it ages ago, without question, and surely there must have been communication with the upper world somewhere not very far off.

Pretty soon we have not only cliffs, but cliffs covered with drifted snow. Do you want to know what the drifted snow is? Why, it is epsom salts. Here we find footprints made by the barefooted boys. May be the footprints were made yesterday, but more likely one-fourth or one-half a century ago. No dust falls here, and every thing remains just where it was put, until some human agency dislodges it.

Wright's Rotunda now opens before us. It is 400 feet across in its shortest diameter. The ceiling is from 10 to 45 feet in height, and perfectly level, the difference in the height being produced entirely by the irregularity of the floor. The lamps fail to illumine these great chambers, and nothing but the Bengal lights can dispel the darkness.

Now we come to the Bride's Chamber. Once, a long time ago, a fair maiden wanted to get married. Her good mother objected, however, and finally exacted from her a promise that she would not marry any man on the face of the earth, without her mother's consent and approval. Then the two fond ones went down into Mammoth Cave and were married there, thus fulfilling the letter if not the spirit of her promise, that she would not be married to anybody on the face of the earth. Many couples have been married there since.

Here we are, at the Wooden-Bowl Room. Wooden bowls are all over the ceiling, turned upside down, only they are made of stone instead of wood. In fact, the whole room seems to be almost the shape of a great wooden bowl. It is also said, that years ago, a veritable wooden bowl was found here in this room. The peculiar formation of the rock, and the character of the water which flowed through it, I presume, had something to do with the formation of these queer-shaped cavities.

"Danger on the right!" signals Matt, and we crowd off against the left wall, peering anxiously into the thick darkness. Pretty soon Matt lights a roll of oiled paper and tumbles it overboard, and then we can see

what the danger is. Down, down it goes, whirling spirally, lighting up the darkness for a distance of 65 feet. The chasm is about 25 feet across, and over it a dome 55 feet high. Now, then, the Labyrinth, a sort of rude stairway fashioned by nature, lets us go down hill at a pretty steep rate; then we go up hill, then we go down hill, and so we go twisting and turning, up and down, until we hardly know where we are or who we are. Finally a halt is called, and we are permitted to look through a window. Listen! Sure enough, that is water dripping; yes, and we begin to feel thirsty again as we hear the tinkle of a little waterfall. Down go the sheets of oiled paper again, blazing as they fall, and we look down 117 feet, then we look up 100 feet, and this is what is called Gorin's Dome. It used to be called 500 feet; but accurate measurements show it as above. We go back a piece, and then we come to the Bottomless Pit. A bridge goes across it, with an iron railing. The bridge looks as if many feet had trodden it. Before this bridge was built, visitors were obliged to stop here. This Bottomless Pit also extends upward as well as downward. Pensico Avenue is a mile long. By this time we had got so accustomed to wonderful things that I began to take things as a matter of course; and had Matt the guide gravely informed us that the next passage would take us right through the earth, and out into China, in about fifteen minutes, I do not know that we should have been very greatly surprised.

As we passed a great awkward-looking rock, something like one saucer lying inverted over another, Matt hit it with his cane, and said, "Sea-turtle." After he mentioned it, we agreed that it did look like a sea-turtle; but it was a whopper, I tell you. Scylla and Charybdis, two more great pits.

While I was gazing at the wonderful domes that we found above these deep pits, the thought struck me that possibly the sinkholes that I saw the water running into along the railroad track had some connection with these domes. I asked Matt about it, and he said he presumed it was the case. The water flows down in great quantities from the hills, or perhaps mountains, above. It runs into these valleys that I have told you about, sinks into the ground, and keeps on sinking and dissolving the formation until these deep wells or pits with their great domes above them are formed. At the foot of one of these great pits the floor widens out so as to cover about an acre in extent, and in one part of this great room is a body of water.

And now, friends, I have reached the close of my allotted space for this issue, and yet my story is not all told. A great truth impresses itself upon my mind as I go over these details. As we busy ourselves with our every-day cares about our separate little homes, how much do we realize of the magnitude and greatness of this vast universe about us? We know comparatively little of this earth on which we live; and even after we have sailed or traveled over its surface, there are regions beneath its surface, to be explored and to be studied, as I have been

telling you. If this whole earth, then, is but a grain of sand compared to other worlds, what are we, measured by the side of the great God who rules over all? and how little are we able to measure him in his infinite greatness!

Hast thou entered into the springs of the sea? or hast thou walked in the search of the depth?

FRIEND COOK TALKS TO US ABOUT POTATO CULTURE.

AND ABOUT FRIEND TERRY'S POTATO-BOOK.

DEAR MR. EDITOR:—I have read with exceeding interest the A B C of Potato Culture, by T. B. Terry. It is most refreshing to read a work so gushing full of real practical common sense, and from the pen of one who "has been right there" every time, and tells only what he knows, and that the product solely of earnest thought and study, mixed with hard sense. The fact that great gain comes only through great care and painstaking labor, is graphically enforced. Nothing given nothing gained, is God's law. He who reaps without sowing is a thief. Good potatoes, and bushels of them, come only from sweat of brawn or brain.

May I say, Mr. Editor, that every land-tiller could well afford to buy and read this book, even though he is never to raise a potato, as the truths are almost all so broad in their applications? How pertinent to all successful agriculture is the advice to practice thorough tillage, as a fertilizer, a mulch and to irrigate! The talk of manures and their application is admirable. Though it is urged later to buy most products, it is well said that manures should be made, not bought.

The planting in drills is precisely what I do with corn, and largely for the same reasons. Then the Thomas Harrow for early weeding, and, I would add, stirring soil, and thus mulching and irrigating is just what I have proved one of the best things for early weeding of corn, until the plants are two or three inches high. His hints as to selection of seed may well be pondered and practiced by all growers of plants or animals.

The destruction of "Colorado beetles"—not "bugs"—is also well discussed. Certainly no one who can keep the beetles at bay, even at the same expense, should ever use Paris green; how much less, then, when it can be done at half the expense by hand-picking!

And, Mr. Editor, how good those words about hiring the children, and *paying them too!* I was not surprised that so able a potato-culturist should say that he did not know the cause of the scab. If it were from myriopods, as some assert, could so good an observer be ignorant of the fact?

It seems to me that the remarks about handling the crop—in fact, all the well-digested advice of this admirable brochure—would set any one to thinking, in a way to have rich fruit in any line of agriculture.

As I read about burying potatoes, I could not but think of my own words on "clamps" for our bees: "I much prefer the cellar where we can know how matters are progressing." As Mr. Terry says, the cellar storing is less laborious than the burying, which applies also to bees as well.

But, Mr. Editor, if we indorse all this work, we must say amen to the chapter on "Specialty" as well. And then won't brother Heddon claim us as his disciples? While it is best for a man to concentrate his efforts so that all work shall be done in the best way, it is also equally desirable to have a variety in just so far as it does not prevent this excellence of execution. We all know that a change in work means recreation.

A. J. COOK.

Agricultural College, Mich., May 8, 1885.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT.

EDITOR AND PUBLISHER.

MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, MAY 15, 1885.

Let nothing be done through strife or vainglory. PHIL. 2:3.

THE A B C of Potato Culture is meeting with a most gratifying sale. Price 35 cts.; by mail, 38 cts.

BEESWAX.

UNTIL further orders I will pay 25 cts. cash, or 2 cts. in trade. This is to take the place of the advertisement on the cover of the last number.

UNTESTED QUEENS.

THE demand has opened up beyond the supply, as is usual during this month. The way they are *now* coming in from the South, however, we shall soon be up with the orders.

THE BEE BUSINESS PROGRESSING IN ARKANSAS.

We notice by one of the papers, that Mr. Anthony Opp, of Helena, has sold to Mr. Robert J. Adams, of Chicot Co., Ark., 200 colonies of bees. But a short time ago Mr. Opp made a shipment of 50 colonies to another customer in Chicot Co. The price paid for the 200 was \$4.50 per colony.

THE WINTER IS PAST, AND THE SUMMER IS AT HAND.

A GREAT many reports in regard to winter losses are at hand; but the season has now come when we must turn our attention to something else than talking over our wintering troubles; therefore let us drop wintering for the present, and take up honey-getting.

IMPROVEMENT IN SIMPLICITY SMOKERS.

Friend J. A. Green, of Dayton, Ill., suggests that the Simplicity smoker is made much handier by having a stop for the door so it shuts down and strikes firm when the opening for putting in the fuel is closed. He makes them by chopping a nick in the circumference of the bottom of the fire-pot. We do it by putting in a tinued rivet, allowing it to project enough to stop the door.

ERRATA.

In the advertisement of G. J. Flansburgh, in our issue of April 15, his initials were printed E. J. Please note.

On page 300 of our issue of May 1, 23d line of first column, we made Prof. Cook speak of beetles looking like little *bugs*. As a matter of course, he meant to compare the beetles with the *bugs* that fall off.

On page 317, friend J. H. Brown says: "The mice destroyed the rest; all came out right." He meant to say, "The mice destroyed one; the rest came out all right." This, however, was the fault of the manuscript, and neither editor nor reader could make any thing else out of it. Please don't make a straight mark for *one*, friends.

THE A B C OF CARP CULTURE.

I HAVE often decided that I would never again advertise a book or any thing else until I had got it in my hands. Well, the above book was so near finished, months ago, that the greater part of the proof-sheets were in my hands. For some unknown reason it does not make its appearance. The A B C of Potato Culture is having a nice sale, for which we extend thanks.

TOBACCO.

AFTER the doctors decided that Gen. Grant could not get well, he just went and got well himself; or, at least, he is able to be around, as I suppose you all know. I presume you all know, too, that he has stopped using tobacco; and may it not be that the discontinuance of tobacco of itself has had something to do with his recovery? I have been wondering whether he ought not to have a smoker with the rest of the brethren; but then, I do not know whether he is a bee-keeper, and so I have not as yet decided to send him one.

PACKING PLANTS NICELY TO GO BY MAIL.

Our thanks are due to C. Weckesser, of Marshallville, O., and A. T. Cook, of Clinton Hollow, N. Y., for sample plants. The first was three Miner's Proflic strawberry-plants, that opened up as fresh as they were when taken from their places in the garden; in fact, one could almost imagine that the dew yet lingered on their bright-green petals. Friend Cook sends us some splendid specimens of Houghton gooseberries and Golden-Cluster raspberry-plants. I should say, that both of the above-named friends understand their business of mailing plants, to a dot.

COMBS WHERE THE BEES HAVE DIED.

SOME of the veterans may get tired of hearing this old story over and over again; but there are others, a host of A B C scholars, who keep inquiring about it every spring, especially after such a mortality as has just come over our land. Your combs are just as good as they ever were, even if there are dead bees in the cells, and the combs have been neglected until they smell badly. Just put such combs, one at a time, in the center of a good strong colony, and the bees will fix it in a twinkling. Don't put too many in a weak colony, at one time, or the bees may get disgusted and swarm out. But a strong colony will take one or two at a time, and make them nice and sweet in four or five hours. It is a good plan to shake the dead bees out of the empty hives, so far as you can handily. Don't melt your combs up for wax, if they are good straight worker-combs. The honey that is contained in them will come in excellently for building up new colonies; and if you do not think it is wholesome for another winter, manage so as to have the stores consumed in rearing young bees.

OUR OWN APIARY.

At this date, May 6, the bees are getting loads of pollen and considerable honey from the soft-maples. We usually have fruit-trees in bloom by May 1, but this year they will be a week or ten days later. By the way, it seems to me due credit has never been given the maples, for the reason, probably, that we so seldom have our bees strong enough to do justice to them when they are in bloom, and many times they come in pretty nearly with fruit-

bloom. Yesterday, while we were plowing down by the creek, with our new plow, "Solid Comfort," the bees were just roaring among the maple-trees. It seemed almost as if we were at work in an orchard in full bloom. When a thunder-cloud came up, the bees poured toward the apiary so as to make a good deal such a roar as in basswood time. I tell you, it is pleasant to have a hundred or two of *strong* colonies at a time when we used to have spring dwindling. Our bees have no disease of any kind, and we have not had a dwindle, unless it was a colony that got soaked by a cold rain when a cover of the hive blew off, and even that was carelessness.

May 14.—Here it is, and not a fruit-bloom yet to be seen; but the bees are just roaring on the hard-maples. Two hundred booming colonies get up quite a roar in the month of May, I assure you. The pounds of young bees that have to be shaken from their combs, however, to be put aboard of every train that leaves our depot, effectually extinguishes any thought of swarming. With the amount of business we are doing in bees by the pound, I fear our 200 colonies will not keep their strength very long; no, not even with another hundred purchased from neighbors Rice and Shook to back them up. We shall soon begin to have reinforcements of new swarms from the farmers round about, however, and we hope to keep up our reputation for prompt shipment.

BUCKWHEAT FOR SEED.

Just about this time of year our troubles commence on orders for buckwheat. Do you want to know why on buckwheat more than other seeds? It is because it is quite bulky, and of but little value. We offer common buckwheat for seed now for \$1.25 per bushel, or 35 cents per peck. Somebody away down in Texas orders half a bushel; it weighs 25 lbs., and is worth only about 65 cents. If we send it by mail, it would take over \$3.00 worth of postage-stamps; if by express, the charges would be from \$1.00 to \$1.50; by freight, perhaps as much. The best way we could fix it, the charges would be a good deal more than a bushel is worth; and we have been obliged to make arrangements with all railroad and express companies, to pay all charges when our customers refuse to pay them, to prevent having them stopped on the way. Whatever is shipped with a card on, showing that it came from A. I. Root's establishment, we want every express company and railroad company in the world to understand that A. I. Root is good for the charges, even if the man to whom it is sent is not. Now, then, what are we going to do? It is quite customary to order seeds by express, after the ground is all ready; and some men always take whatever they order, no matter if the express charges are \$2.00 on 50 cents' worth of seeds. But there are other men, generally those new to the business, or those who are not very well posted in regard to business rules, who will let a thing lie in the express office until it is sold for charges, whenever such charges are more than they expected. If the one who orders such bulky seeds that cost but little would just add, "I know the express charges will be heavy, but I am prepared to pay them," how pleasant it would make every thing! Do you not see the point, friends? We like to serve you; it is a pleasure to jump and run to execute your orders; but we hate to be burdened with heavy losses as the reward of our alacrity.

FOR SALE!

40 Colonies of ITALIAN and HYBRID BEES IN CHAFF HIVES.

Price \$150. cash for the lot, to be taken at the apiary.

J. H. PEIRCE,
104 DAYTON, MONT'G Y CO., OHIO.

MICHIGAN POULTRY FARM.

W. R. & I. S. PHILLIPS, Proprietors,
BATTLE CREEK, MICH.

Breeders of only pure stock, White and Brown Leghorns, Black Cochins, Langshans, Wyandottes, and Silver-Bearded Polish. Prices clear below other breeders for the same quality. Eggs from \$1.50 to \$3.00 per 15. Stock for sale in season. For large orders, write for special discount. No circulars.

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or \$2.00 per year.

\$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or \$2.00 per year.

Those whose names appear below agree to furnish Italian queens for \$1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with * use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for \$1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

HELP FOR THE SUFFERERS.

The following friends have agreed to furnish bees and queens at low prices, for the benefit of the friends who have lost badly during the past severe winter. In consideration of this, they are allowed to give the following notices once free of charge. As will be noticed, the prices are more or less lower than our regular advertised rates.

After June 1, I will sell a few 2-frame nuclei with tested queen at \$4.00, Simplicity frames, wired and built on fdn. with brood, bees, and honey for the trip. Shipped in light boxes.

CHALON FOWLS, Oberlin, Ohio.

I will supply those who have lost their bees, with a few hybrid queens at 50c each; queen with ½ lb. bees, at \$1.00; bees by the pound at \$1.00. Safe arrival guaranteed.

WM. H. CATHER, Ashville, St. Clair Co., Ala.

If any of the friends who have lost bees the past winter, and wish to try again will write me, I will quote them prices which can not fail to be satisfactory. I have a few colonies with queens from Heddon stock, and three or four hybrid colonies; also pure Italians, about 15 in all, to spare. First come first served.

R. J. FOX, Natick, Middlesex Co., Mass.

During the months of June and July I will sell 2-frame nuclei of Italian and hybrid bees, with untested Italian queen, one frame to contain brood, at \$2.25. Italian bees by the pound, \$1.00. Satisfaction guaranteed.

MRS. A. F. PROPER, Portland, Jay Co., Ind.

After June 1, eight colonies Italian bees, with untested queen, from imported mother, \$5.00 each. Bees, \$1.25 per pound. Untested queens from imported mother, \$1.00 each. After Aug. 1, 80c. Safe arrival guaranteed.

J. W. CRENSHAW,
Versailles, Woodford Co., Ky.

I will sell 25 strong colonies of hybrid bees, with laying queens in 10-frame Root's Simplicity hives, at \$5.00.

M. LAFORREST,
Thibodaux, Lafourche Parish, La.

I have three colonies of 8 frames each for \$4.00 each; they are hybrids, or dark Italians. The reason I have them for sale is, they are not in Simplicity frames, so I shall dispose of them at the above prices. Price cash, one or all, to suit customer; no contagious disease in the State that I know of. Send money by money order to Arcadia, Crawford Co. S. C. FREDERICK, Coal Vale, Craw. Co., Kan.

I will sell, during the month of May and June, bees by the pound, at \$1.00. Two L. frame nuclei and queen, \$2.00. I guarantee safe arrival.

W. R. WHITMAN, Nashville, Davidson Co., Tenn.

I will sell, and deliver at Otsego express office, 50 colonies of bees, mostly Italians, queens reared from pure mothers, 9 straight worker combs (Adair frame) in hives, for \$7.50. Q. frame nucleus in L. or Adair frame, with bees and brood and untested queens, in July. The above queens are reared from imported mother, Root's importation, in light box, for \$3.00. I will do by you as I would wish to be done by.

CALVIN LOVETT,
Otsego, Allegan Co., Mich.

WE WILL SEND,

June 10th to July 15th, untested queens for 90 cts; after, to Sept. 1, 80 cents. Tested queens, \$1.50; choice, \$2.00. Bees, 1 lb., untested queen, \$1.50 now. Postal notes (no stamps) on New Iberia, La.

SAFE ARRIVAL GUARANTEED.

J. W. K. SHAW & CO.,

LOREAUVILLE, Iberia Par., La.

BEES & QUEENS

At greatly reduced prices. After June 15 I will sell 2-frame nuclei, with 2 lbs. of bees in each, no queen, for \$2.25 each. Tested queens, \$1.50 each; warranted queens, \$1.00 each; untested queens, 75 cts. each, either Syrian or Italian. F. E. GOOD, SPARTA, TENN.

DADANT'S FOUNDATION

HONEY COLUMN.

CITY MARKETS.

NEW YORK.—*Honey*.—At present, sales of comb honey are very slow; and owing to the lateness of the season we do not anticipate any change in prices until the new crop commences to arrive. We quote at present prices as follows:

Fancy white clover, 1-lb. sections, per lb.	14@15c
Fair to good " "	12@13c
Fancy " " 2-lb. " "	13@14c
Fair to good " " 2-lb. " "	11@12c
Fancy buckwheat, 1-lb. " "	9@10c
" " 2-lb. " "	7@8c

Ordinary grades not wanted.

Extracted white clover, " "	7@8c
" " buckwheat, " "	6@6½c
<i>Beeswax</i> , prime yellow, " "	32@33c

May 20, 1885. McCALL & HILDRETH BROS.,
34 Hudson Street, corner Duane St., New York.

NEW YORK.—*Honey*.—There is no notable change in the honey market. The demand is light for both comb and extracted, and prices are now ranging very low. We quote:

Fancy white clover, 1-lb. sections, per lb.	14@16c
" " " " 2-lb. " "	12@13c
Lower grades, 1 and 2 lb. " "	10@14c
Buckwheat, 1 and 2 lb. " "	7@9c
California comb, fancy white, " "	10@11c
" " extracted " " in 60-lb. cans; 6½@7c	

Beeswax,—30@32c, according to quality.

THURBER, WHYLAND & CO.,

May 13, 1885. Reade & Hudson Sts., New York.

CINCINNATI.—*Honey*.—There is no new feature in the market. Our regular customers only are buyers at present. There is almost no outside demand, and low figures are no inducement. We quote extracted honey from 5@8c on arrival, and comb honey from 9@12c.

Beeswax is in very good demand, arrivals are plentiful. We quote 24@25c for good yellow on arrival.

CHAS. F. MUTH,

S. E. Cor. Freeman and Central Avenues,
May 10, 1885. Cincinnati, Ohio.

BOSTON.—*Honey*.—We have not any thing of interest to note about the honey market; prices remain the same, and our stock is light.

May 21, 1885. BLAKE & RIPLEY,
57 Chatham St., Boston, Mass.

ST. LOUIS.—*Honey*.—Honey is difficult to sell. Extracted Southern, in bbls., held at 4 to 5c. Choice Northern in kegs, 7@8c. Comb honey nominal, entirely neglected.

Beeswax. No change to note; orders scarce. Quote from 27@30c. W. T. ANDERSON & CO.,
May 21, 1885. 104 N. Third St., St. Louis, Mo.

CHICAGO.—*Honey*.—Comb honey is in light demand at 12@15c for best grades; not much on the market. Extracted dull at 5@7c. *Beeswax*, quiet at 25@27c. R. A. BURNETT,
May 20, 1885. 161 So. Water St., Chicago, Ill.

CLEVELAND.—*Honey*.—There is no change from our last report; sales are very slow, and only the brightest, most attractive lots are moving at 14c for 1-lb., and 12@13c. for 2 lbs. Second qualities stand perfectly still. *Beeswax*, 28@30c. A. C. KENDEL,
May 20, 1885. 115 Ontario St., Cleveland, Ohio.

BEE-KEEPERS,

We are making very nice ONE-PIECE SECTIONS, and are selling them very cheap.

Please send for price list.

FLORIDA.

ORANGE-GROWING, BEE CULTURE, & GARDENING. FOR SALE,

Near Lane Park, Sumter Co., Fla., on the east side of Lake Harris, near shore, and in the famous "Great Lake Region" of the "Orange Belt," about 10 acres of choice first-class pine land, with portion of rich Hammock, right of way to the lake, and advantages for boating, fishing, bathing, travel, and transport. Soil exceptionally good, and admirably suited for orange-growing, or raising early fruits and vegetables. Excellent bee-pasturage surrounding. Location pleasant, healthy, well protected from frost, near two important towns and R. R. stations, and in desirable and rising neighborhood. Good home market for produce, and first-rate facilities for transportation. An excellent opportunity for advantageously uniting the above three industries. Each should pay well singly, and by combining them, early and good income may be secured before the splendid result gained when the grove is brought into bearing. Title perfect. Price moderate. Fuller particulars and terms from

W. D. CAMPBELL, Tavares, Orange Co., Fla.

NOTES FROM THE BANNER APIARY.

NO. 66.

CRITICISMS ON GLEANINGS.

EDITOR GLEANINGS:—We fear that in our criticisms on GLEANINGS we pained you and many of your readers by including religion in the list of subjects that we would have eliminated from GLEANINGS. For fear of doing this we hesitated, when writing our last article, about adding religion to the list, but did not see how we could consistently avoid it. You, of course, feel it your duty to follow the course that you have adopted, and we ought to, and I think we do, have charity enough not to *blame* you, even though the course does not meet with our approval. We sometimes wonder if we are not *too* outspoken. If we have any criticisms to make, we make them openly, "right to a man's face," then he can explain, or defend himself. This may not be the best way to make or to keep friends, but it is "our way." We have very generously been allowed to point out what we consider the faults of GLEANINGS; we now hope to be allowed the pleasure of enumerating its excellences. First, it is always *out on time*. When we are expecting a welcome guest, how much greater the pleasure if he comes when we expect him; and how annoying the disappointment if he does not come *on time*! Second, it always comes *well dressed*. It has a good cover, is well printed upon good paper, and almost entirely free from typographical errors. This may not be so important as that it should contain valuable *ideas*, but it adds greatly to the pleasure of reading it. Perhaps we are oversensitive in regard to typographical

neatness; but a publication that is lacking in this respect arouses in us a feeling that is akin to disgust. Third, it is lively, spicily, wide-awake, and interesting. Even if it does "mix things up," it is seldom *dull*. Some have condemned that "everlasting foot-note" that usually follows each article. There may be objections to it, but, in one respect at least, it is, in *our* opinion, a good thing. If its editor is "up with the times," beginners are less likely to be misled by the errors, fallacies, or wrong conclusions of correspondents.

ARGUMENTS VS. PERSONALITIES.

We were much pleased with your remarks upon page 308 in regard to discourteous criticisms. *Arguments* never hurt; invective and offensive personalities often do. Let us turn over a new leaf, and all join hands in henceforth keeping our apicultural literature free from offensive personalities.

RAISING AS MUCH COMB AS EXTRACTED HONEY.

In reply to Mr. Smith's query upon this subject, we have nothing to add to what we have already written, unless it be to fill the sections with *fdn.* and give no more room in the brood-nest than an ordinary queen *will* keep full of brood.

NAMES AND ADDRESS UPON SHIPPING-CRATES.

We have been informed that most commission merchants are opposed to producers putting their names or addresses upon their packages. Let some of the commission brethren "speak."

8—W. Z. HUTCHINSON, 68—40.

Rogersville, or Genesee Co., Mich.

In regard to the foot-notes: Whenever I think an article is in any way misleading, I expect to correct the tendency to the best of my ability, and I am very well aware that some writers have felt grievously hurt be-

cause of my foot-notes; but for all that, the greatest good to the greatest number, in my opinion, demanded them. Many times a brother gets carried away with some special idea. For the time being his head is not quite "level," as it were. Well, if allowed to go out that way, without anything to modify it, or to tone it down a little, it might be misleading. It is very true, that my judgment may be in error, for it would be strange if it were not, occasionally. In that case it is a misfortune, I admit; but to avoid such misfortunes, I have at my elbow about all the bee-journals published in the world, and all the treatises on bees, of any account, in print. Besides this I have the benefit of the communications that have been sent to me for 15 or 20 years past, in regard to bee culture; and I am self-conceited enough to think that my memory is seldom at fault. My daily prayer is, that God may give me wisdom, and may keep my heart from egotism or prejudice. One or two of the friends have complained because I did not add some comment of some sort at the close of their communications; and if I should drop my time-honored custom, friend H., some of the brethren would not know I was *alive* any more.

SHIPPING BEES.

Putting $\frac{1}{2}$ lb. of Bees and a Queen on Combs where the Bees Died from Honey-dew.

MRS. CHADDOCK TELLS HOW IT WORKS.

THE two half-pound packages and the two queens came through all right. They were put up in *very* good shape; only 25 dead bees in one package, and 80 in the other. They came to the express office on the night of the 20th, and I brought them home yesterday, and turned them loose on some combs of honey-dew and bee-bread where the bees died last winter. By the way, it seems to me that these are about the tongueiest bees that I ever saw; or was it because they were thirsty, that they ran their tongues out so far and so persistently?

We were coming home — Minnie and her papa on the front seat, the bees and myself on the back, when I happened to look over on the end of the packages, and I saw what I thought were hundreds of legs sticking through the screen; then I thought it could not be legs, but wings, and I called Minnie to look, and she said it was tongues. And it was; hundreds of long slim tongues running out, and waving round; and they did this only on the side where the wind struck them. It was too funny to see them running their tongues out to cool them, like a thirsty dog.

This morning Bro. Phillips came up to look at them. He wants to send for some, but is afraid of getting cheated, and I went out to the hives. "Why," said he, "these bees look weak; they can hardly fly." I looked, and, behold, there they were crawling out from the entrance to the edge of the alighting-board, and then rolling off, their bodies swelled up tight as a drum, and stretched out to their longest capacity. I knew in a second what ailed them, but I said, "See what nice large bees they are," and I took off the cover and showed him the cluster; he said they were *very* large indeed.

He went home; and as soon as he was gone I went and looked carefully around the entrance, and there were dozens of those *nice large bees* lying on their backs, kicking their heels up in the air, and I snatched that honey-dew out of the hive, and gave them some fresh honey taken from another hive, and since dinner I have looked at them again, and the swelling has gone down, and they are perfectly sober. The honey-dew was dripping from every pore when I put them in. I tasted it, and it was a little sour; but I thought that, as they could fly out all the time, it would not hurt them. I looked closely, and could see no dead bees near the hive, so I suppose they all recovered.

MAHALA B. CHADDOCK.

Vermont, Ill., May 22, 1885.

Thanks for your report, my friend. My opinion is, that a good strong swarm would have managed those combs, dripping with sour honey-dew honey, all right; but they might have turned around and swarmed out, going off "lickety-split," holding their noses. To prevent such a catastrophe as this, I think it will be better to hold fast to the oft-repeated injunction — put such combs, one at a time, in the center of a good strong colony, till you get them all purified and sweetened. — I think it likely the bees were sticking their tongues out because the day was hot, and they were suffering for want of air. Whenever they do this, shade them from the sun and put them in the wind. They will usually draw their tongues back in a short time. Bees after a trip like this are in poor condition to work up sour honey. Much the better way is to put so small a quantity of bees as half a pound on a comb of healthy brood taken from some other hive. A whole pound of bees will do very well without this comb of brood; but with so small a quantity as that mentioned, it is apt to be "nip and tuck" before a reinforcement of young bees begins to hatch out. I do not believe I should want to recommend only half a pound of bees to start a colony in a hive containing empty combs. Even if they do make a live of it, a frame containing a little brood would give them a great lift, just at a critical point.

REPORTS ENCOURAGING.

HONEY FROM THE WILLOWS, AND THE WAY IT COMES, ETC.

I WENT into winter quarters with 38 stands — 37 in cellar, one outdoors in double hive. All came out alive; lost two queens this spring after they commenced laying, and had brood. They had dysentery some, not very bad. I put an upper story on with Hill's device, and put muslin cloth over the frames, and covered with clover and timothy and chaff, which I got in our feeding-room. May 10th the bees commenced work on the willow. On the morning of the 12th, before the bees commenced to fly, I had one of my best colonies of hybrids on a scale. In the evening they had gained 6 lbs.; 13th, 10 lbs.; 14th, 4 lbs. Then the willow bloom closed. In 1883 the willow flow was good; 1884, none; 1885, as above described. Now, how much honey do you suppose they gathered?

Conrad Grove, Iowa, May 25, 1885. G. J. KLEIN.

Thank you, friend K. Ten pounds a day from the willow, I should say, is very extraordinary. It seems to me that willows must be very plentiful where you are. We were aware that it yields honey largely, but did not know it came in at the rate you mention. If the colony on the scale was an average one, your apiary must have gathered two or three hundred pounds in a single day.

A GOOD REPORT FROM FRIEND BLOOD.

Our home apiary has wintered, as usual, *without loss*. The colonies have been evened up, and the last week all brought in honey freely from willow and maple. I am glad to see that you have a man in charge of your bees who is a *bee-keeper*. In the past ten years we have lost bees twice. One winter they had a short supply of honey; and as we were away from home, about one-fourth starved. At another time we tried to winter several small colonies which should have been united. These two experiments are all we need. Now, how do we winter?

1. *We are very sure that every colony is strong in young and vigorous bees.*

2. *That they have more than enough good honey to last them till spring.*

3. *All upward ventilation is closed, and eight-inch entrance at bottom wide open.*

4. *All hives are double-walled on sides and bottom. One-fourth inch above frames is a one-inch-thick honey-board which the bees wax down.*

I should add, that we do not extract honey, neither do we use the bees in raising queens during the summer. I think we feel as sure of our bees being alive in the spring as we do of our hens. We use the L. and Gallup frames, about an equal number of each. There are more dead bees on bottom-boards of L. hives than of the Gallup. Strong colonies winter well on L. frames; smaller ones on the Gallup.

A. H. K. BLOOD.

Quincy, Mass., May 8, 1885.

NEW HONEY IN ALABAMA.

Some of my hives have upper story chock full. I hived a new swarm on Apr. 2d on empty frames; gave them upper story of sections at once. I have taken 80 full sealed sections from it, and have two frames, 8 boxes each, ready to take out now. How is that for work?

J. J. DAVIDSON.

Grand Bay, Ala., May 2, 1885.

ONLY 4 LOST OUT OF 88.

I am still out of Blasted Hopes. The 88 swarms that I put in winter quarters came out in fine condition, except that two died, and two have dwindled from loss of queen, leaving 84 hives of bees at this date.

JOHN CLINE.

Fayette, Wis., May 15, 1885.

GOOD PROSPECTS.

After my report on page 318, May No., I lost three more colonies of bees by dwindling; two more are pretty weak. The rest are in good condition at present. Some have ten frames with brood, with plenty of bees to gather honey, if any were fit for use. Apple-trees, strawberries, dandelion, and buckeye-trees are yielding honey at present. Buckeye makes fine honey; but honey from the other sources is not good, especially what is gathered from willow, which will be in bloom in a few days. Bees will be in better condition to gather

clover honey when it commences, than they were last year; I am in hopes I shall be able to secure a fine crop of honey the coming June and July.

Linna, Ill., May 14, 1885. J. A. THORNTON, 73-69.

THE MAN WHO WINTERS BEES BY THE HUNDREDS OF COLONIES,

AND WHO WINTERS IN SPITE OF THE HONEY-DEW STORES, ETC.

OUR friends will find a picture of the writer of the following on page 437, Aug., 1883. Learning that he had again wintered his bees without loss, I wrote him a letter, asking him for particulars. Below is his reply:

I can do but little more than acknowledge the receipt of your letter of inquiry, and refer to a detailed description of "How I winter my bees," published in GLEANINGS of Oct. 15, 1883, p. 536. I have made no material change in my manner of wintering.

My bees are in a prosperous condition; the outlook for the season is very promising at present. I have three large apiaries to care for and look after, with at present but one assistant. This I am sure will be a sufficient apology for not trying to add one more to the voluminous list of articles on wintering bees.

Yes, I wintered in spite of honey-dew. Not only had I thousands of pounds of it in my winter stores, but I fed up several colonies upon it after taking away every thing and giving them only empty frames or foundation, and these without exception wintered in perfect condition as well as the very best.

Mr. S. F. Newman, of Norwalk, visited two of my bee-houses in March. A few words from him in regard to that visit might not fail to be interesting.

East Townsend, Ohio.

H. R. BOARDMAN.

Thanks, friend B.; but we should have been glad of a longer letter. Friend Newman, you see you are called on. Please tell us about that visit. I have just turned to the page mentioned above, and read again the description of the way in which friend B. winters his bees. Several things have impressed me by reading it. The first and most important one is, that this matter of wintering is within our control. Where one man winters his bees successfully year after year, while his neighbors lose fearfully during these same years, it is pretty good evidence that it is the man and the management, rather than disease or even a "happen so."

Another point that impresses me is, that these old hands at the business may each of them winter quite successfully, and still be unlike in their methods of management; that is because each one has learned by experience what he can do and what he can not do; and each one may have a peculiar fashion of his own for accomplishing the same result. Friend Boardman, as you notice, winters indoors, and others get along just as successfully by wintering out of doors. May be the stores consumed in the latter case are, however, an objection in the way of expense. Friend B. also favors artificial heat as a means of ventilating his winter repositories. Another point, his hives

are entirely without bottom-boards during winter, being raised up on two 2x4 scantling. Where this great amount of ventilation is allowed, of course the room must be pretty well above the freezing-point. Friend B. prefers 45°; and if he can not keep it up to 45° without artificial heat, the artificial heat is used.

SOMETHING ON THE OTHER SIDE.

FRIEND HIGGINS' REVIEW OF GLEANINGS.

BRO. ROOT:—Mr. Hutchinson's remarks on the "Contents of Bee-Journals" brings me to my feet. I feel I have a grievance also, as well as well-merited praise to bestow, which will be approved by bee-keepers generally. I find fault with "I think" and "don't you think?" and all such generalizing that betrays both ignorance and inexperience. I find fault with those who say, "I am right, but you are wrong," simply because we don't agree. I find fault with that bee-keeper who gets angry, and wants to use the columns of a decent bee-journal to call another hard names, and abuse him just because he chooses to honestly contradict a statement justified by his own experience; and I never will take a bee-journal nor any other paper that has for one of its special features the privilege of its columns to slander the character of others. I object to this mud-throwing by bee-keepers because their views are not swallowed without objection, right or wrong. I object to a bee-journal being restricted exclusively to bees and nothing else. Bee-keepers are not restricted entirely to keeping bees. Our lives are diversified by various occupations in connection with bee-keeping. One has poultry, another gardening, and perhaps some may have carp culture and silkworm raising also.

The driest thing that we of the South can read about in the bee-journals is the quarreling over the hibernation theory, tree-trunk wintering, the pollen theory, and whether Mr. Heddon or some other man should or should not be sainted for discovering it, if the discoverer can ever be designated. We do not care how you winter in the North, so such reading-matter is all paid for and no value received. We don't care any thing about Mr. Heddon's hive, nor any other hive in particular, so long as it has the L. frame and admits of easy manipulation.

For myself, I don't care a cent for what Mr. Hutchinson says about raising comb honey, for I raise only extracted; yet Mr. H.'s articles are of almost priceless value to thousands who do. These things are almost all superfluous to us of the Mississippi Bottom in particular; yet no wail that I know of has gone up from this section, protesting what you ought and ought not to put into your columns. We of the Mississippi Valley have a claim on GLEANINGS, and insist that it ought to be national in its character, and comprehensive in its scope to meet the demands of bee-keepers. We do not want it to be monopolized by any certain class of writers, nor restricted to any certain class of writing, but to be national in character, and comprehensive in its reading-matter. We of the South can not be especially interested in the pollen theory and wintering problem, but we like to know how the world is moving among our bee-friends, and have their experiences in all matters.

Our Homes is objected to by some, and delights

others. Your Juvenile Department can't interest an old bachelor very much, but is a source of great joy to the families of many bee-keepers. So, Bro. Root, on behalf of thousands who hail with gladness each issue of GLEANINGS as it is, go on and keep it as it is; and let those who wish, read only the articles on bees, and they will have more than received their money back, and the rest of us will go on and read the rest. After our editor of GLEANINGS has finished his work in this life, and goes up higher to his reward, there will be the general verdict, "Well done; who can fill his place?"

I began with 75 colonies (68 queens), and have now 132, of which 128 are laying. I have sent, so far, 4½ barrels of new honey to Cincinnati. We have the worst weather in thirty years, cold and wet. I am 28 miles from New Orleans. CHAS. M. HIGGINS.

Hahnville, La., May 20, 1885.

HOW TO MAKE A HOME-MADE WATER-PROOF.

WORKING IN THE RAIN, AND NOT GETTING WET.

A FEW days ago a warm drizzling rain set in—just what we had been watching and waiting for. When it commenced, all hands were set at work to put out the plants that had been waiting in the greenhouse for such an opportunity. Pretty soon it began to be almost too wet to work, without danger of getting a cold. One of the men suggested that we should get some pieces of oil cloth, make a hole in the center for the head to go through, and that this covering would protect the shoulders and lungs, with a part of the arms, so that it would be safe to go on with the work. I suggested our enamel cloth as being just the thing. In a twinkling, one of the girls in the sewing-room had made a water-proof cloak. You want a piece two yards long, costing 40 cents. Make a hole in the center, something like a button-hole; hem it all around, and then put on a button, so as to button up close to the chin. Round off the corners so they will not be dangling around in the way, and put on a string so as to draw the loose folds back under the arms. If you are to be out long, roll up your sleeves so they will not feel disagreeable, and you are ready to set out plants, take care of bees, or do whatever you choose.

The boy who was dropping plants thought he ought to have one, so a smaller one was made for him. With his trowsers rolled up, and barefooted, he stayed out through every shower, without any inconvenience.

A great many times when work is pressing, we are tempted to stay out and do it, and thereby we sometimes get a cold that throws us out of days or weeks of time, in the most critical part of the season. With such a cloak or roundabout we have saved it all, to say nothing of possibly saving valuable lives. If you do not succeed in making one to your satisfaction, from directions given above, we can send you a sample of one fixed as we have it, for 75 cts.; 10, \$6.00; 100, \$50.00. If wanted by mail, add 25 cts. extra for postage. Children's size will be 50 cts.; 10, \$4.50; 100, \$42.50. If wanted by mail, the postage will be 20 cts. extra.

SOME NOTES AND COMMENTS.

FRIEND W. F. CLARKE TALKS ABOUT HIBERNATION, BEE-JOURNALS, AND SOME OTHER THINGS.

THE last two numbers of GLEANINGS have been very suggestive of topics on which to write; and to discuss them fully it would require more time than I have to spare, and more space than I dare venture to ask. But there are two or three matters on which I must beg leave to offer a few words.

CHILLED BEES.

Friend Doolittle has given us an interesting account of some experiments, as to the degree of cold bees will bear, and the length of time they can stand it. But I just wish to say, that chilled bees are not hibernating bees, or bees to which I have applied the term hibernation. A chilled bee, like a shivering human being, is in a condition of discomfort and uneasiness. The state of hibernation, semi-hibernation, quiescence, torpor, semi-torpor, or whatever term may be applied to the well-known condition in which bees remain closely clustered, exercising their functions but little, and eating the *minimum* of food, is a state of comfort, contentment, and rest. A chilled bee is on the road to death; its progress thither may be arrested by timely warmth; but if not so arrested, the result will be fatal. A hibernating, torpid, dormant, or whatever-you-like-to-call-it bee, is in the path of life. The first effect of too much cold on a bee is to rouse it to unusual activity; the second, to induce over-eating; the third, to make it give up, get numb, and gradually succumb. Like a human being overcome by extreme cold, a chilled bee becomes motionless and insensible. It may be roused out of the first stages, and restored by warmth; but if let alone, it will infallibly die.

THE JONES FRAME.

On page 264, where a cut is given of this frame, the idea is conveyed that it is the one generally in use among Canadian bee-keepers. This is incorrect. Owing to Mr. Jones's well-earned fame and influence, his frame is extensively used; but many of our best bee-keepers prefer the Langstroth, or a modification of it. Mr. Hull, of Woodstock, perhaps our largest producer of comb honey, uses a frame rather larger every way than the Langstroth, but preserving very nearly its proportions. Most of our hive-makers manufacture the Simplicity hive, and it is in wide demand. I think Messrs. S. Cornell and Allen Pringle use the Quinby frame, or a modification of it. Dr. Thom, I understand, is experimenting with the Jones frame, turned the other way about. A few Canadian bee-keepers use the American and Gallup frames. In fact, we have a great variety of frames in use—the more's the pity. Beginners in bee culture here, as elsewhere, are prolific of ideas in regard to hives, and aspire to be inventors before they have won their spurs as apirists. I think I am correct in saying that the Jones and Langstroth are the two prevailing styles of frames; those who produce extracted honey preferring the Jones, and those who go into comb honey, using the Langstroth.

PROFESSOR COOK.

Our good friend Cook shows an excellent spirit under what he meekly calls the "just flagellation." I gave him about his *ex-cathedra* pronunciamento concerning hibernation; but I am surprised to find him falling into the same errors as unscientific

writers, in overlooking the fact that hibernation is a thing of degrees. This fact is recognized by Kirby, the great authority whom he quotes, who says: "Every gradation is to be met with between ordinary sleep, the imperfect or abnormal hibernation of some animals, and the profound hibernation of others, in which all the functions of life are suspended." I have never claimed that the hibernation of the bee is "profound, but only imperfect and abnormal." Assuredly, in the case of the bee, "all the functions of life are not suspended," but it can not be denied that *some* of them are when the close, compact winter cluster is formed which we all know to be so desirable. I believe that bees cluster in this way when they have satisfied their appetites for the time being, and unclasp when the demands of hunger make it necessary for them to eat again. I think they feed only at certain intervals, when in a normal wintering condition. How long or how short those intervals are I do not pretend to know; but I fancy they are decided to some extent by the weather, and that bees take the opportunity of eating when a mild spell comes. This is one reason why I prefer outdoor wintering, instead of the uniform temperature maintained in a cellar or bee-house. By the way, notwithstanding his expressed and no doubt sincere desire not to be dogmatic, Professor Cook is, as you say, a little too much inclined to get into the rut of positive assertion. Thus, in quoting Kirby he makes the great naturalist say, "Bees do not hibernate." But on turning up the reference to *Kneip, Brit.*, I find that what he really says is, "Hive-bees probably do not hibernate." Prof. Cook no doubt quoted from memory; but it would seem that his recollection, like his utterances, is apt to run into a positive mold. He is right in saying that reporters at conventions, in their study of brevity, are apt to give our expressions "too sharp a twang." But in my "just flagellation" I quoted his own deliberately penned language in the *A. B. J.*, where he said, in reply to a query, "Bees never hibernate." His quotation of Kirby, too, was penned by himself. "*Litera scripta manet*"—"What is written, stands."

THE MIX IN GLEANINGS.

Has not the editor given himself away a little in his reply to friend Hutchinson on page 309? I think so. He says, "GLEANINGS is not devoted *entirely* and exclusively to bees." We all know that. But the title-page on the cover says, "Devoted to bees and honey." That motto around the flying bee is no part of the title of GLEANINGS. It rather indicates the spirit in which the busy little insect makes its flights; and sad experience compels me to say that it has not a feeling of good will to men universally, for it stings me on every favorable and unfavorable opportunity. I think the Scotch motto, "*Nemo me impune lacessit*"—"No man meddles with me with impunity"—would be more applicable. I must say I rather sympathize with friends Smith and Hutchinson in their criticism on the varied contents of GLEANINGS; but if you are bent on making your journal a miscellany, would it not be better to amend the title on the cover in some such way as this: "Devoted to Bees, Honey, etc.?"

THE POLLEN THEORY.

Friend Heddon has sung his triumphant psalm in GLEANINGS; but there is one difficulty, at least, to be surmounted before we can all join in the chorus, "See, the conquering hero comes!" It is the "dry

feces." What is that brown and black powder which collects beneath the frames when bees winter well? Following Quinby, I have strongly maintained that it is "dry feces." Mr. Heddon quotes Prof. Cook as positively denying this. Well, then, what is it? If not "dry feces" it must be rejected pollen and other waste matter dropped by the bees when they are feeding. If it is "dry feces," we have proof that bees can safely eat pollen during winter confinement. If it is rejected stuff spit out by the bees while feeding, it shows that, in a right condition, they will not eat pollen to their injury during winter confinement. Either view is fatal to the pollen theory, and we are forced to the conclusion that, after all, safe wintering is a matter of temperature. If that is right, bees can either eat pollen with impunity, and pass it safely, or they will not eat it at all, so that we need give ourselves no trouble to keep pollen out of the hive in winter. Fix them so that they can hibernate, quiesce, "keep asy," as Paddy would say, or whatever you like to call it, and pollen in the hive will do no harm. I may add, that I have sent Mr. Heddon a sample of "dry feces," received from Mr. Corneli, also another taken out of one of my own hives, requesting that he will get Prof. Cook to analyze them with the same care that he has done the wet feces, and I am waiting anxiously for the report. If it does not knock the pollen theory into a cocked hat, "call me a Dutchman."

WM. F. CLARKE.

Speside, ∞ Ont., May 7, 1885.

Friend Clarke, I thank you for your kind criticism, and I for one feel guilty; but what *my* conscience accuses me of is this: In letting a good deal have place in GLEANINGS that not only has little or no reference to bees, but matter that occupies space that is of no particular benefit to any one. May God give me grace to do better, and to set a better example; and to commence at once I will cut this short right here.

HOW TO MAKE A HONEY-TANK.

A TANK ALL OF WOOD TO HOLD OVER 1000 LBS., AND NOT TO COST OVER \$7.00.

ON page 310 I see that Mr. Ross, of Texas, wants to know how to make a honey-tank. I have used one made of wood for two years, and am well pleased with it. It is about 6 ft. long, 2 ft. wide, and 18 in. deep, with a V-shaped bottom, and holds 1000 or 1200 lbs. of honey. It is made of 1-inch and 1½-inch pine lumber. The end-boards are grooved into the bottom and sides so that the latter extend beyond the former about 3 in. The other joints (i. e., where the boards are spliced) are grooved and tongued together, and all the joints are cemented together with white lead and canvas. It is put together with screws—not nails. It is painted on the outside, and coated on the inside with paraffine, which is, I think, much cheaper than tin, and just as good, so far as I see. Six small iron rods go across the tank, to prevent it from spreading when filled with honey. I place the extractor and uncapping-box on the tank, have a hole about a foot square in the cover, in which is placed a piece of cheese-cloth for a strainer. The honey from the extractor and uncapping-box flows through this strainer into the tank, and is drawn off at the bottom by means of a honey-gate placed in

one end, whenever a customer calls for it. The tank is mounted on legs, so that the honey-gate is about 18 in. from the floor of the honey-house. Of course, I have a stool to stand on while extracting. My tank is not stationary. I had a carpenter make it to order. It cost me something over \$7.00.

Bangor, ∞ Iowa, May 6, 1885. M. A. JACKSON.

Thanks, friend J. No doubt the above arrangement will answer very well. There is one reason, however, why I should not like a wooden tank coated with paraffine, as well as one lined with tin. Any utensil in which honey is placed is apt to get a sort of strong odor in time, and nothing removes this so effectually as boiling water. Tin can be cleansed with boiling water without trouble; but boiling water would dissolve your paraffine, and make mischief. If you have had it in use some time, however, and have not noticed any slight taint given to the honey, after it has stood in it for some time, perhaps my fears may be groundless.

A BEE OR A BUG—WHICH IS IT?

PROF. COOK TELLS US SOMETHING ABOUT AN INSECT THAT OFTEN FREQUENTS OUR BEE-HIVES.

I SEND you by this mail a specimen of a bug or bee, and I should say both; but I never heard of a bug-bee. I got hold of one of your ABC books, and bought 11 swarms last fall. I have 5 swarms now. Do you think I read my ABC's well? The insects I send I found one in one of the hives, and the others on the backs of worker-bees. They are very active, and jump on the bee's back, and fasten their sharp pincers in the bee's neck, and the bee can not fly with him, but runs every way to get him off; but he sticks in spite of all. I did not wait to see how soon he would kill the bee, but took them off. I never heard or saw anything like it before. It may be because I never kept bees before. They have no sting, but the slickest pair of pincer jaws I ever saw. With the bug-bees, I inclose a few dead young bees. The old bees drag them out and they appear to have the St. Anthony's dance, and are deformed. Do you think it is by being chilled, or is it some insect at work at them? The bug-bees eat sweet like a bee. What are the specimens, and cause of the deformed young bees, and what gives them the St. Anthony's dance?

Wakeman, Ohio, Apr. 20, 1885. R. DERBY, JR.

In submitting the above letter to Prof. Cook I suggested that perhaps these little bees were the same that bore in the pithy stalks of the thistle and mullein.

PROF. COOK'S ANSWER.

The little black slim bees are species of *Andrena*. They have a tremendous sugar-tooth, like almost all bees, and, like some higher animals, prefer to steal their living rather than to procure it by honest toil. From their small size, quick motions, and hard crust, which latter serves them as a natural shield, they are able to brave the anger of the hive-bees. To see these little fierce bees pounce upon our large honey-bees, reminds us at once of our sparrows and blackbirds as they worry our large hawks. These little bees, like our honey-bees, are hardly robbers from choice; for as soon as the flowers come they mend their ways and gather their own stores.

You are not correct in supposing that these bees nest in hollow stalks, though very near relatives do.

These dig tunnels in the earth, where they deposit stores and lay their eggs, and where their young are reared. Sometimes their tunnels are sunk some inches in our hard walks and roads.

These bees annoy the honey-bees some in early spring, but I do not think need cause any alarm.

A. J. Cook.

Agricultural College, Mich., Apr. 24, 1885.

As friend Cook does not mention the bees that seem to have the St. Vitus dance, I would suggest that it is the same malady described in the A B C book, at the close of the article on the diseases of bees. Of course, the little bee described has nothing to do with the diseased bees.

FIVE FRAMES IN A HIVE.

WIDE FRAMES NOT YET THINGS OF THE PAST, ACCORDING TO FRIEND DOOLITTLE.

ON page 247 of GLEANINGS for April 1st, Mr. E. W. James asks what I do with the remainder of the space in the hive where I use but five or six frames, when a new swarm is put into a hive. In all of my hives I use but 9 Gallup frames, although the standard Gallup hive is made to hold 12 frames. Some years ago I ascertained that queens as they would average would not give me brood amounting to more than 8 frames full, so I gave 9 frames, as the amount of one frame was needed for the pollen and a little honey, before the sections were put on. To bring the standard hive down to 9 frames, I used 3 division-boards, making each one take the place of a frame; and when new hives were made they were made for only 9 frames, so that at present writing I have few of the standard hives on hand. In this way I was enabled to secure a much larger yield of comb honey than I ever could with the 12-frame hive, as, when such was used, I always found the 3 outside frames filled with honey at the beginning of the honey harvest, which gave a tendency toward crowding the brood-nest with honey, rather than an immediate entering of the sections. After a while I ascertained, by many careful examinations, that the queen of a prime swarm would, on an average, keep only from five to six frames filled with brood for the first six weeks after being hived, after which the brood-nest was gradually reduced to less size until there was no brood on the approach of winter. After having ascertained this I gave each new swarm but five or six frames, and secured results from new swarms never obtained before; but instead of using division-boards, as friend Root supposes, I use wide frames of sections on each side of the brood; for by so doing I get the surplus honey (which I used to get in the frames) placed in sections, which is just where I want it. Those who have decided wide frames are not the things to use will never fully realize the possibilities of bee-keeping, in my opinion.

The great secret of a large yield of comb honey is getting the sections as near the brood, both at sides and top, as possible, and I know of no arrangement that meets these requirements so well as wide frames. After sending off and getting nearly all the case arrangements mentioned in our bee-papers, so as to make a careful comparison of them with wide frames, to-day finds me more in favor of wide frames than ever, and I do not believe, taking the year through, that the case system has any advan-

tage over the other, regarding the saving of labor, which is the main plea used in their favor. Before throwing away wide frames, I advise all to read the short article from F. J. Farr, found on page 313.

WINTERING.

On page 246 friend Root thinks that bees in chaff hives will not die if fed heavily on sugar syrup, and desires the particulars if any have so lost. I have given the particulars in GLEANINGS and A. B. J. regarding one so lost, so I will not go over the grounds again, but will simply say that, upon now going over my bees after a loss of one-fourth, with another fourth very weak, I can see no difference in favor of sugar syrup over honey. The difference in favor of chaff hives is quite marked, yet they are not wholly exempt from loss, by any means. On page 303 I find that it is thought that the "Linswik" sisters' success is owing to the extra care they gave their bees. Let us see: A friend calling at my house several years ago remarked to myself and Mr. Betsinger, who chanced to be here, that there was no need of losing bees if the proper care was given them when preparing for winter, for he had never lost any, and did not believe he ever should. B. remarked that his turn would come yet, and, sure enough, to-day finds him with 20 weak colonies left out of 70 last fall, despite the extra care he says he gave them. Another friend who does not claim to use any great care, and who brimstoned some 20 colonies last fall, because he had more than he wished, came out of this winter with every one alive, he being the only one in this section who has not lost heavily; so I say that we—I don't know any thing about what makes our bees die. Last fall I packed with extra care two colonies sitting side by side, each having the same number of combs, of the same age, queens of the same age, bees and stores equal, and all as near alike as two peas, yet one died before March 20th, while the other is the best colony I have in the yard to-day. Now, friend Root, when you or any one else will tell me why the one died and the other lived, then I will tell you how to winter bees; and until some one can do this, I shall be excusable for saying I don't know.

G. M. DOOLITTLE.

Borodino, O. N. Y., May, 1885.

Just one word in regard to what you say about sugar syrup compared with honey, friend D. It was but a few days ago that I decided, while running over my letters for copy, that there was no further need of publishing letters showing the great advantage of winter stores of *sugar syrup* over winter stores of honey. Our bee-journals have given proof again and again, year after year, until I should say the matter is settled. It is true, there are those who write that they have not noticed any thing in favor of sugar syrup over good honey; but these letters do not account for very much while the fact remains that no one of late years claims that honey is *better* than sugar stores. Once more: The large stores of honey-dew have, without question, been the death of thousands of colonies. Had these bees been fed on sugar syrup instead of honey-dew, they would have been saved. Almost all the bee-men in Medina County have lost terribly. Their bees had such stores as they gathered; ours, such as we fed them. They lost fearfully, and their bees are dying of spring dwindling, even up to this present time, dur-

ing the latter part of May. There has been nothing like spring dwindling in our apiary. We fed barrels and barrels of sugar; they didn't.

BEES IN CUBA.

HONEY FROM THE BANANA, ETC.

IN GLEANINGS of Dec. 1 I find an inquiry as to why bee-keeping in the tropics is not a success while bananas are grown largely. In this locality, and in a radius of two or three miles, there are many thousands of banana and palm trees, each of which blossoms a "racemos," or cluster of blossoms, which average 3½ ft. in length, with a diameter of 2 ft. across the shoulder—a solid mass of creamy-white blossoms, upon which the bees, when other stores are scarce, actually swarm. They are never neglected, even when the campana is in bloom. There is also a tree here called "digame," which is a mass of white blossoms for two or three weeks, at this time of the year, and I should say a very ordinary bee-keeper could make a success, in this province at least. The others I know nothing of but from hearsay, which reports honey everywhere and all the time.

We are situated about six miles from the town of Principe, which is connected by a railroad of about 45 miles with Nuevitas, a port on the north coast, and one of the finest harbors in the island. Vessels sail from there to New York, and make the trip in from 8 to 14 days. A good steamer could do it in 4.

The climate is most lovely, the thermometer averaging about 80° in the day to 76° at night. I never saw it below 70° the coolest night I have experienced; but that was in June, when one would suppose it to be the warmest of the year.

The people are the most hospitable I ever met or heard of. When you are introduced to a Cuban at his home he says, "My house is yours; do what you please with it;" and I verily believe, that if you could pick it up and carry it off on your back, the Cuban would climb a tree and rest satisfied that he had carried out his hospitality in the sense it is understood by his people. All of the women are beautiful, and as amiable as lovely; in fact, I am yet to see a woman or child with any other disposition than that of a smiling and pleasant one.

The soil is the richest on earth; and if the Spanish government carries out the spirit of the letter of their treaty with the United States, this island will be as near a paradise for the producer as can be found on this earth. By irrigation, plants can grow the year round. As it is, two corn crops are grown on the same field in one season, extending from April to December; but with the agricultural machinery of the United States, three could be obtained. The cultivation of the land is done in the most primitive manner. The plow that Moses might have used is still in use here. There is not a four-wheeled wagon in the province. The carts, and all labor of that description, is done by oxen, and I shouldn't be surprised if these oxen were cotemporaries of Moses also. Every thing is done in a very old way; but when an American gets down here they think they have a circus right on hand. The comments upon their ability to carry out any thing except in their way is very amusing, if not flattering. But they find the American is "not the kind of cat" to back out of any thing he undertakes. When we commenced to set up our hives, and talk bees, hon-

ey-slinging, floating the farm in it, and sailing a canoe in it from here to town, they claimed we could not do any thing with our new and improved methods. Now we are showing them about it, and the astonishment of the visitors that come here to view the "circus" makes us smile. Neither Heddon nor Hutchinson would ever get the stomach-ache if some poor fellow started his toes on the edge of his field, as I think there is no limit to the amount of bees that can be kept by one party. One elderly gentleman visited us, who, when younger, kept 1000 of the native hives, with a banana plantation of 40,000. He stated there was money in it. He now owns 66,000 acres in the island, worth \$800,000.

WM. H. WOOD, C. E.

Puerto Principe, Cuba, Dec. 26, 1874.

HONEY-DEW, ONCE MORE.

ARE WE TO HAVE A REPETITION OF THE TROUBLES OF LAST SEASON?

EDITOR GLEANINGS:—Would it not be well to call the attention of bee-keepers to the matter of the bark-lice (*Lecanium*), and the sweet excretion from them? These lice are very common again this season. They are now to be observed as small but rapidly growing scales on the under side of the branches of the trees. We find them here very abundant on white-ash and bitternut, and quite so on basswood, sassafras, and maple. They are now sucking the juices from the tree in such quantities as to greatly injure them. At the same time they excrete the sweet substance which lures the bees. Last week I saw the bees thick about the lice-infested branches. Later, the blossoms of the maples and willows have attracted the bees to more wholesome nectar. It behooves us to keep a close watch, that we may know if the bees are storing or have stored this unsavory sweet, that we may extract it in case it has been gathered to any extent, that it may not be mixed with our white-clover honey. Such precaution would have saved hundreds of dollars to the bee-keepers of the country last year. This nectar secretion, if rightly managed, may and will prove only a benefit. It will stimulate the bees to greater activity, and may be used to feed in early spring, or any time in the summer, if care be taken that it is not stored with honey to be marketed, or with the winter stores.

Mr. Editor, have you never wondered why this secretion was poured forth by these scale lice? I think I have the solution. These scale lice are degraded insects, and so mimic the bark of trees in color, and are made so inconspicuous by their flat form, that they are protected largely from birds and other insects. Thus they gain by their lowly plain habit and mode of life. There is no physical energy required to move about, and so all is used to increase reproduction, and hence the immense prolificness of these bark-lice. But real virtue, even when garbed in plainest dress, can not always remain hidden. That these lice have virtue, is manifested in a phenomenon which has pleased us very greatly the last few days. Some chipping sparrows and Baltimore orioles have been licking up these lice by the thousands. The beautiful golden orioles will take a limb and pass its whole length, and scarce leave a louse. It is very interesting to see them taking their several meals from a favorite

tree right against our house. Now, how poorly these lice are equipped for defense against such a raid as this! Yet they have an armor of no mean value. It is this very habit of nectar secretion. The nectar attracts the bees and wasps, and the bees and wasps frighten off the birds and other insectivorous animals, just as Prof. Tuleare has suggested that the cotton secretes sweet from extra floral glands to attract wasps and ants, which keep off the ruinous caterpillars.

How wonderful the laws that have led to the development of such wonderful methods for safety and preservation! How much more wonderful, and how worthy of reverence, the great Author of these laws!

A. J. COOK.

Agricultural College, Mich., May 16, 1885.

Friend Cook, I am very glad indeed to hear you say that even this matter of honey-dew may, if rightly managed, prove a blessing. It has been a blessing to us in our business of supplying bees by the pound, but I had almost feared to say it, because of being thought selfish. It seems to me it is like all these other things that are unfolding themselves to us day by day as we make progress in studying the works of the all-wise Creator. The very thing that seems a calamity and misfortune may, by the light of science and scientific investigation, be made to minister to our wants. We sell bees by the pound, and start thousands of friends, scattered far and wide, in the industry, and at the same time give them vigorous young bees from late importations from Italy. Now we crowd our work to such an extent that honey-dew and almost every thing else that the bees gather (including the pollen that has been so much talked about recently) is turned into brood and young bees, so that when winter time comes they have comparatively little pollen or honey-dew either. Now, both these substances that ordinarily are but a hindrance in wintering, or even to sell on the market, are turned into bees, and are, therefore, a blessing to us. When we get ready to fix for winter, we have only to fill up with barrels of sugar. Those who raise honey for the market should either choose a locality where honey-dew is not prevalent, or do as you say be very careful not to mix it in with the clover and linden honey so as to injure the sale of this product.

PENNYROYAL AS A HONEY-PLANT.

REPORT FROM NEW ZEALAND.

YOU ask in GLEANINGS, "Does anybody know any thing about pennyroyal as a honey-plant?" Yes, sir; there are acres and acres of it here. In fact, there is not a grass paddock within 20 miles of this, free from it. Some fields you would fancy were nothing else now. When it is in bloom, it is a great plague to farmers, as it is very difficult to eradicate; and once it gets into a district, it spreads with great rapidity. But the honey is the finest, to my taste, of any that I know of—clearer than the best clover honey, and has a beautiful faint mint flavor. It commences to bloom here the middle of January, just as white clover is beginning to fail, and lasts till about the end of February. I don't suppose that it is a large yielder of honey,

as I have got it in but very small quantities each year. I believe it would be a great wrong to introduce the plant to your neighborhood, even if it would yield honey by the bucketful.

R. McPHERSON.

Otaou, Wairou, South Auckland, N. Z., Jan. 29, 1885.

SWARMING AND SWARMING-BOXES.

ONE WAY IN WHICH PEOPLE FORM DIFFERENT OPINIONS.

IN 1878, friend N. N. Shepard, of Cochran-ton, Pa., wrote us a letter, describing his swarming-box, and we published it with the engraving shown below. From the explanatory letter we got, it entered our heads that the pole was put in the closed end of the swarming-box, and accordingly had our picture made. Afterward friend Shepard said it was not right, and would not do at all, and so we had a picture made different, as at present shown in the A B C book.

REPOSITORY FOR SWARMING IMPLEMENTS.

Well, our neighbor Chas. R. Bingham, of Edinboro, O., made us a call to-day, and remarked that he wanted to say that the old style of swarming-box, with a hole in the end, was one of the best institutions ever gotten up for a bee-keeper; in fact, he declares that the implement is sometimes worth half a year's subscription to GLEANINGS, in taking down a single swarm. He just holds the swarming-box right under the cluster, and shakes a few bees into it. All the rest then leave the limb and go into the box, attracted by the humming of their companions. This humming is caused by the loud rejoicing over what they consider a hive, or may be a hollow tree. Now the point is this: Friend B. understood the letter as I did, and made his swarming-box as I had pictured it, got used to having it that way, and now would not have it any other way. He has learned by many years of practice just how to handle it, until the machine is almost a part of himself, as it were. He has got it at his fingers' ends, as we sometimes express it. Well, my opinion is, that had he started with it the other way, and taken a notion to it, it would have answered the purpose just as well. One farmer gets accustomed to a plow; he knows just what to do with it to obtain the result he desires. After he has had it for years, and if he is one of those people who get into a way of doing a thing, may be he will get

along with a very inferior implement in a way which he could not possibly do with a tool greatly superior, and with which he was unacquainted. And this is what accounts for so many different notions in regard not only to implements for handling bees, but tools for doing almost every thing that needs to be done.

The engraving above shows a little shed arranged to contain all implements for taking down swarms. Where we raise comb honey, as almost all of the friends do nowadays, it seems to me such an arrangement will abundantly pay expense.

THE SIMPLICITY HIVE.

A Testimonial in Regard to Its Advantages.

A NEW AND ALMOST UNEXPLORED FIELD FOR INVENTION.

AS I am one of your A B C students I thought I would give you a remarkable instance of the forethought and reflective powers of my bees. I had a Simplicity, which has presented the appearance of being about to swarm for a week or two. About 10 or 15 steps distant, and in the same row, stood a hive full of comb, but no bees except a few dead ones, they having perished for want of honey during the winter, having been robbed too late last year. Four or five days before this Simplicity swarmed, some bees (now supposed to be from the Simplicity) were noticed cleaning out the vacant hive, carrying out dead bees, etc., from it. Day before yesterday it swarmed, and, after much bell-ringing to settle them, the swarm, which was a very large one, settled on the front side of the vacant hive and gradually went right in upon the alighting-board; and before the whole swarm had gone in, numerous workers were seen carrying in heavy loads of pollen.

They are in there all right, and seem to be well pleased, and are working like Turks. Could we not teach this practice to our bees by preparing hives with frames wired and covered with foundation comb, and set from three to five feet high near an apple-tree?

W. J. FARRISS.

Sparta, c White Co., Tenn., May 16, 1885.

Friend F., it would seem from the above little incident that your strong hive sent a committee of investigation to report in regard to the inducements offered by that empty Simplicity hive. This body of bees, composed, of course, of the oldest and wisest heads among forty or fifty thousand, went home and delivered a report something as follows. I suppose the chairman must have stood up, and, after clearing his throat and wiping his face, made his speech: "I take pleasure, friends, in saying that, after having duly investigated matters, it is, in the humble opinion of your committee, the best thing we can do to occupy said unoccupied hive. The hive is a plain simple box—almost as simple, in fact, as the hollow trees used by our forefathers. One especial quality that recommends it to your committee is, that it has no patent moth-traps, ventilators, or any thing of the sort. We find, by careful examination, that we can get in and out easily, and that the man who made the hive has arranged it so that we can gain

access to every part of the hive; and if a miller should undertake to deposit her eggs anywhere about it, we could, a lot of us, take after her and 'scoot her out on the run.' It is the sense of this committee that we move into that hive as quickly as possible, lest some other enterprising colony discover the unusual advantages it affords. Hurrah for the new home!" Joking aside, friend F., reports like yours have been several times given; and the man who will help us to so manage our bees that they will, at swarming time, go right into hives prepared for them, without any supervision on the part of the owner, will confer a lasting favor on the bee-keepers of the world. I have commented on this matter several times before during the years past. There is one happy thought connected with it, which I have hinted at in the foregoing; namely, the possibility of making a hive so much in accord with the notions or instinct of the bees that they would select it in preference to any inducements that a hollow tree might afford; or, in other words, if a colony of bees were to choose, what kind of a hive would they select of their own free choice? or was it the empty combs that took their fancy? or have they, in fact, any notions in the way of preference as to how their hive and its surroundings shall be arranged?

WINTERING.

Have we or have we Not made Progress in regard to this Matter?

ALSO SOMETHING ABOUT THE POTATO-BOOK.

IDO not know that I should have ordered a copy of your A B C of Potato Culture, had not Brother W. Z. Hutchinson kindly mailed me his to read, as he states on page 335. I certainly can not say less of the work than to indorse all that Bro. H. and Prof. Cook say in praise of this praiseworthy book; though, like Bro. H., I never expect to raise a potato, I knew I ought to have a copy of my own. I felt sure that such reading would benefit me many times 38 cents' worth, let me follow what occupation I might.

I think Bro. Doolittle is decidedly mistaken in thinking that we have gained nothing in our experiments and controversies regarding the pollen theory and wintering problem. He evidently does not understand it as I do. He closes by saying, "What do we know on these points, any way?" I will answer him, by saying that I have always been among the more extensive losers of bees during winter; that I have never at any time before believed that I had the problem settled. I fully believe it now; and if, in the future, I turn my own tables and become one of those who "never lose bees in winter," will Brother D. not willingly admit my claims? Were it not, as you mention, perhaps best to drop this subject just at present, I could explain wherein lies the difference between my failure of the past and proposed successes of the future. All this, however, can be discussed in due time.

JAMES HEDDON.

Dowagiac, Mich., May 18, 1885.

That is the kind of talk, friend Heddon, Just keep cool, and prove your position by wintering bees all right next winter, and the

winter after that, and so on. Such a result will be more convincing than pages of theorizing.

ANOTHER REPORT FROM FRIEND OSBURN.

BEE-KEEPING IN THE TROPICS.

FRIEND ROOT:—In drawing the line of comparison as viewed from the standpoint of the apiarist, do not let us place it too far north or too far south. Do not let us paint it with too much sunshine on one side, and nothing but gloom and disaster on the other. The North to-day stands pre-eminent before the world as a honey-producing country. Its white clover and basswood enjoy positions as honey-producing plants that time will not efface, or the fame of the white sage or bellflower detract one single point from their usefulness. The proud position that apiculture in the United States holds before the world will never be superseded by any other country or set of people, for it is backed up by too much of the spirit of enterprise and never-fail disposition, that has made the U. S. what they are.

In view of these facts (which are stern facts) would it be wise to say that, because the North has cold winters, that prove disastrous to the business in some localities, that the business will be abandoned, and the enterprise which has assumed such grand proportions, declared a failure? We think not; no, the American people *never* fail; rebuffs and setbacks may come; "but, as sure as the sun rises to-morrow morning," they will rebuild the structure on a firmer foundation than before, and "try, try again."

Let us leave the North now, and rest (fully assured that she can take care of herself), and come down to Cuba, and see what the prospects are for success in modern apiculture south of the frost-line. Although we have been here now only 18 months, we feel justified in saying that the country has many resources and advantages, for the honey-producer, that no country north of this that we have ever seen does possess. First among them is the large amount of honey that there is here; and in proof of this let me say, that at this writing we have 555 colonies, all in one apiary (shall make them 600, and all doing well. Second, there is no winter here. But you will ask me, what about our dearth of honey, and of our disaster last year; i. e., the loss of so many colonies? To which I will say, that our great loss was only the result of too much increase, and ignorance, on our part, of what the honey resources of the country were at that time of the year. If you will remember, last year we increased from 34 to 520. Any apiarist will readily understand that, after such an increase, that pretty much all the colonies were weak when the flow from the flowers stopped. But now the situation is very different. Instead of all weak ones there are 400 colonies with their top stories on, and full from top to bottom of bees and honey, and we have two months yet to go before the dearth comes, for the other 200 to breed and store moderately along, until the flow ceases altogether. But suppose those that have not honey now to carry them through the dearth do not get it, we have a large surplus in the 400 to fall back on, and there will be no need of letting any of the weak ones starve.

We are making preparations not so very much

unlike what we would for a northern winter, only this difference: Our colonies can fly every day, and they will be at all times so that we can examine them and know their condition.

There is one source of trouble here in the summer that the Northern apiarist is bothered with but little, and that is the moth. As soon as the colony becomes weak, the miller will go in and deposit her eggs in spite of the Italian or Holy-Land bee. That is, when there is a hive full of combs, and only bees enough to cover three or four, the miller will go in, in spite of them. But after all the disadvantages are summed up, when you take into consideration that there are 8 or 9 months out of the 12 to raise bees and gather honey, it is not so bad a place for the apiarist after all. And then, too, colonies will build up faster here than in the North, for the weather is warmer. It does not take as many bees to keep the brood warm; the queen can lay more eggs, and there are more bees to gather honey. The comfort of the apiarist, while handling bees under these sheets, is ahead of any situation out of doors, for there is no sun nor rain nor dew to annoy him. With hat off, a low pair of shoes (no stockings) a pair of overalls and shirt, with shirt-sleeves rolled up to the elbow, we work with a large degree of comfort.

Now I will tell you about the fleas, for "there is no rose without its thorn." During the dry months they are a pest. While a fellow is flying around he minds but little about them; but when he comes to sit down, then they bite just a little for fun; but they do not keep us from sleeping. We sleep soundly, and the sleep is refreshing. However tired we may be when we go to bed, we get up in the morning feeling as though we could dance a horn-pipe. I have been in the mountain districts of California and Arizona, that were renowned for their health-giving elements; but never have I found a spot where sleep would so perfectly restore the wasted energies of the system, as right here in this portion of Cuba. Is not the reason clear? A narrow strip of land set out in the ocean is fanned by a continual breeze that carries in its very breath health and long life.

A. W. OSBURN.

San Miguel de Jaruco, Cuba, W. I., May 7, 1885.

A NEW DEPARTMENT ASKED FOR IN GLEANINGS.

FRIEND MALLOY GIVES HIMSELF A SEVERE LASHING.

MY last performance in the bee line has almost discouraged me. I will relate the circumstances; and if you never have had a department for *fools*, you may prepare one for my benefit. Two weeks ago my bees numbered 16 hives; to-day the muster is 14, all told—eleven Simplicities and three box hives. Two weeks ago the weather was warm, and the bees were out in force. I threatened every day for a week to examine the hives and see what condition they were in; but being very busy it was put off till Friday evening, when I concluded to look into them. The first hive looked at was in the last stages of starvation—all dead but about a teacupful. I made some syrup as quickly as possible, and sprinkled them all over. I don't think I ever saw any thing that affected me more than their weak efforts to use their tongues and fail in the effort,

and fall from the combs motionless into the mass of dead bees on the bottom of the hive. Before I was aware of it the robbers were on hand, making things lively, I shut up the hive, and left. The next hive (box) was entirely gone; every bee dead. The remainder appear to be all right. Now, where the fool part comes in is this: Some of these hives are two stories, and the top one with ten frames all solidly full of honey. I went into them to see and know they were full, with perhaps a single row of cells running diagonally from top to bottom that the bees have emptied, or perhaps never filled. Now, what ought to be done with a chap who neglects his business so shamefully as this? Suppose Henry Bergh should have a lieutenant here in Missouri, what is to hinder him having me pilloried before the public as a warning to bee-keepers everywhere? I don't know that he could, but I feel that he ought to any way. If putting a horse in a stable and leaving him there until he starved to death is "cruelty to animals," what is it to let a hive of bees starve with a surplus of honey on hand? Of course, I did not know that they were starving, neither did I put myself to any trouble to find out, and consequently have no excuse whatever to offer.

P. A. MALLOY.

Arno, 5 Mo., March 24, 1885.

I am glad to see you so willing to confess your sins, friend M., and may be the lashing will hit a few others besides yourself. It is a shame, I agree with you, for a bee-keeper to starve his bees when he can give them enough in fifteen minutes to last them as many weeks. Just think of it! only a minute a week demanded by each colony; and then in the face of that, to let bees starve to death in the spring of the year! I think Mr. Bergh had better come and settle where bee-men are.

A NOVICE'S EXPERIENCE WITH QUEENS.

A CHAPTER FROM REAL LIFE.

WE began the spring of 1884 with five fair colonies. They built up well, and the first swarm issued May 24; soon came a second and third swarm from the same colony. The other colonies swarmed at intervals until the middle of June. We began to find our young queens missing; they ventured out, but never returned. Then we gave eggs and young larvae, and tried to rear queens. One colony reared a large fine-looking queen, but she had imperfect wings. We discovered her at the entrance of the hive with bees around her, evidently anxious for her flight. Several times we saw her looking over the field. At last we caught her and gave the bees a frame of larvae. For some reason they did not succeed in rearing a queen.

We now had four or five colonies queenless, and began to think of some redress. A friend in Farwell gave us a very nice-looking queen. We sent to A. I. Root for a dollar queen. She came, a small dark-looking one. We succeeded in safely introducing her, and watched her progress. The brood looked patchy, and the bees seemed to die more than from other colonies. We pronounced her "no good," and thought, when spring came, we would supersede her. The spring has come; the bees seem working well, and the queen has improved so

much in appearance that we have changed our opinion.

We had read "Alley on Queen-Rearing," and concluded, with the credulity of a child, that if we could get some Alley queens we should revolutionize things. We sent to Alley for two queens—one a tested queen, the other a warranted selected one, and the *Apiculturist*. The queens came, nice-looking ones, and directions for introducing them. Surely we shall now succeed. We gave the tested queen to a colony that had long been queenless, following directions. She was balled—the bees utterly refused her. We caught the queen, and in our efforts to cage her she flew away. Our dismay can better be imagined than described. We looked here and there. Soon we saw, from the commotion of the bees on the frames outside the hive, that the queen had returned. This time we caged her and tried introducing her in a Pect cage. It was of no use. The bees would have none of her.

We now tried another colony; and when all seemed right we let her run down the frames. We kept a careful watch, and soon found all was not right. In our attempts to secure her this time she was lost indeed—we have always thought she was stung to death. The warranted queen we gave to a nucleus, and she was gladly received. She did well through the fall, and we thought we had a treasure. Her bees suffered severely from disease last winter, but I felt sure, by contracting the brood-chamber, they would build up. A day or two ago I examined the colony, and found bees enough only to cover the palm of the hand. The queen looked dilapidated, discouraged, and forsaken. I immediately gave them two frames, with bees and larvae in all stages, not being able to find full frames of brood with bees just eating through. Undoubtedly it was a bad case of spring dwindling. We await results.

After our loss of the tested Alley queen I sent for another, stating expressly that I wanted it to rear queens from, and would send more money if needed. A queen came that was safely introduced. The fall was mild. The other queens were laying, but this queen seemed idle. I wrote to Mr. Alley, inquiring about her. I received no answer. After a time she did rear a little brood, and we had hopes of a better result in the spring. In February the bees from this colony seemed restless, looking for something they could not find. In a day or two I found the dead queen outside the hive. In April this colony was united to a very weak one that came through with a queen and a corporal's guard.

At present they seem to be doing well. My hopes of rearing queens from the Alley stock are blasted. The *Apiculturist* has ceased to visit me, and I give our experience in the hope that some beginner may realize how unsafe it is to "count the chickens before they are hatched."

M. A. P.

Friend P., it does seem from your little story as if bee-keeping were a precarious business at best. It seems to me that, if we could get down to it, we should find the key to all your troubles to be that you had violated some simple rule in bee culture. For instance, I can not understand how it is that you lost so many queens unless you set your hives too close together. If it should transpire that you set your whole four, together with the new swarm as it came out, all close together in a row (on a long bench, for in-

stance, as we often see them, then it would be very plain and clear why you had such troubles with your queens. I watched carefully while going over your article, to find mention somewhere that you had the A B C book or some other guide to go by. If you have not, your first duty is to get one. Taking a bee-journal will not compensate for the lack of a good treatise on bees. Our bee-journals take it for granted that their readers are posted on the fundamentals before they commence taking a journal. Should we do otherwise, it would be a constant repetition of the rudiments of the science year after year.

SWARMING TIME.

AND THE WAY NATURAL SWARMING GOES MANY TIMES.

I HAD 5 swarms from 6 stands; saved 4, all large ones too. Had rather lively times last Sunday. One new swarm I put in a box gum until my Simplicity hives could get here. Well, I tried to get them into a Simplicity, but go they would not. So on Sunday they came out and settled nicely, and then I got them into the Simplicity hive. About that time a new swarm came from one of my box hives, and settled near the others; and by the time I got them fixed, another came out of another box hive, and settled in two trees. Well, I fixed a Simplicity hive for each, and shook them down, when they both got into one hive. Well, about that time an absconding swarm of my neighbor's came over, and they, too, went into the hive. Now a commotion was caused, and the second swarm began to be troubled, when it and the first one from the box hive I had been trying to get into a Simplicity hive went together; so, instead, as I first thought of having four hives with five swarms, by night I had only one hive of bees. They all went together before sundown, and on Monday, by 9 o'clock, they were flying about as if they all intended to swarm and get righted up. But, no; they (a great many) went back into the old box hives they came from, but left a great many bees in the Simplicity.

At dark I took a look into the hive; and, upon my word, the Simplicity was chock full of bees. Only one frame out of the 14 I could get out. The bees were clustered over the rest and clear to the bottom of the hive. Do you think the swarm from the box hive I was trying to get into a Simplicity hive could have united with the absconding one, and the other two young swarms went back to their parent hive? I can not see how else they could have done. It puzzled me considerably, now I tell you.

Please tell me how long they will begin to store honey in the section boxes after they swarm and are put into a Simplicity hive; and what do you think of my putting a board over the old box hives, with a hole or holes open over those in top of box hive, and placing one of the honey-crates and boxes on, and cover with half-story cover? Think they will make me any box honey that way? I should not like to try to transfer them until I get a little more used to them. I thought I would try that plan this summer any way.

R. J. WATERS.

New Madrid, Mo., May 14, 1885.

Friend W., just such troubles and mixing-up of matters is pretty sure to ensue where

natural swarming is allowed, and this is one reason why I do not like it. I should think the most of it was caused because your hives were full, and your bees had no room to work. Boring holes through the top of the box hive is not quite the thing. It does not afford opening enough, unless there are a great many holes, and they are pretty large. Better pry off the top of the box hive and set your case of sections right over the combs. If the bees have been some time in the box hive, there will be no danger of the combs breaking, even if the whole top is removed entirely. When bees get the swarming mania there is no accounting for what they may do. They will push out and push in everywhere, under all circumstances, and get all in a heap, as yours did, and I do not know how to lay down any very precise rules of management. A better way is to be sure that our bees have plenty of room, and by this means discourage swarming as much as we can.

REPORTS DISCOURAGING.

REPORTS DISCOURAGING FROM IOWA.

I HAVE been looking in GLEANINGS for a report from Iowa, descriptive of our present condition in the "beebusiness," but I found none. I suppose the brethren all feel too bad to "get up and speak in meetin'." The losses of the past winter exceed any thing ever before known in this section. Three-fourths of the bee-keepers lost all. The few that remain are mostly miserable weaklings. Out of 69 I saved 30; only 6 of that number are in good condition; five of the latter are in chaff hives. Every few days we "git a sarm," but after every "sarm" we have one "sarm" less. The severe winter accounts for the trouble. Our winter set in Dec. 2, and continued almost solid until March 26. From Jan. 1st to April 1st we had only 9 days that the mercury stood above freezing at 7 A.M. On 25 days during that time the mercury showed below zero at some time of day. From Jan. 15th to 22d inclusive, from zero to 20 below; from 9th to 13th inclusive, from zero to 18 below. From Feb. 15th to 23d inclusive, from zero to 18 below. Jan. 21st, 7 below zero at 2 P.M. Feb. 12th, 12 below zero at 1 P.M. No supplies wanted. If this doesn't do for Blasted Hopes, I would suggest that you send some one to Greenland to try bee-keeping.

G. B. REPLEGUE.

Udell, Ia., May, 1885.

TURNED OVER THE BEES TO THE WOMEN, AND GONE TO FARMING.

I am not a fit subject for Blasted Hopes, but my hopes are "busted." I went into winter quarters with 52, and I now have 13; those 13 I turned over to a female friend of mine who writes her name Mrs. Snyder, and I have gone to farming. If I should get the bee-fever again, I will let you know by sending for goods. The bee-keepers in this part lost fully 75 per cent.

F. L. SNYDER.

Orion, Wis., Apr. 25, 1885.

The winter of 1879 put me in Blasted Hopes. The past winter puts me there again, along with most of my neighbors. I have a nice lot of combs to use in building up. I shall have my hives full by July.

15—J. P. C. STEDDOM, 15—4.

Webster, Ind., May 11, 1885.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

ADJUSTING THE SPACES SO AS TO PREVENT HAVING
BITS OF COMB BUILT ON THE OUTSIDE
OF THE SECTIONS.

HAVING had some experience in the production of comb honey, I thought I would venture to write you a few items of my past experience. My first experiment was to prevent the bees daubing the sections with bits of comb and propolis, as it seemed to be my greatest trouble. I found, by changing the regular space of $\frac{3}{8}$ inch between the brood-chamber and honey-boxes, or crates, to $\frac{1}{2}$ inch, or just enough space to admit a passage between, I could prevent them from building those little bridges of comb. Next I made my crates deeper, so I had the same space between the top of sections and cover as between the brood-chamber and sections, and I found they would stick their glue, or propolis, around the joints of cover. By following the above plan I can say it gave me entire satisfaction.

JACK ELLIS.

Grantslick, Ky., March 2, 1885.

A HOME-MADE CIRCULAR HAND-POWER SAW.

I have been making a hand-power saw by your directions, which works so well I will tell you about it. To drive it I got an old horse-power wheel, about five feet in diameter, fitted a carriage-axle to the bearing, and bolted the axle to two posts. I turn it by a pin in one of the spokes. When I tried it I did not like the bevel gauge, for the part of the board that had been cut would cramp the saw. Then I made one to slide in place of the cut-off bar, with a strip at the back edge to rest the lumber against. This works splendidly. I also changed my cut-off bar by having the cross-piece double the front one worked by two set-screws so that it can be changed to any angle. This works very nicely too.

Your A B C is the best book I ever saw. I would not be without it for any thing. I have been very successful with bees, and have never lost a colony by wintering. I started with Langstroth hives, but have given them up for Simplicity.

E. S. LEA.

Brighton, Md., March 5, 1885.

PREVENTING BEES FROM SWARMING OUT, WITHOUT A DRONE-TRAP.

When a man has not any frames of brood to give a swarm to make them stay in the hive, why not shove it back on the bottom-board so the bees can just get in and out, or use a Jones drone-guard, or something to keep the queen in the hive until they get a start at work, and then you can give them more room? I suppose you have thought of this before, but I have never seen it in print. I am here staying through the winter, and am trying to help some in bee culture. It is in its infancy here at present, and bees can be bought in old gums for \$2.00 and \$2.50; but I think it will be quite a business after a time. I can not see way it won't. There are orange groves going out every year, from one to 50 acres, and they yield more honey to the single flower than a bee can carry. I shall try it until the last of May, and then go north. I cut a tree 7 feet through last week, and took out a swarm, and they were not going to stay, and I had to clip the queen. I had one of your hives, and shoved it back until the bees could just go in and

out, and then they went to work. Oranges are just blooming here, and I am going to see what I can do with them. I will try for 100 lbs. comb honey.

Silverton, Fla., March 9, 1885. A. W. LINDSLEY.

Friend L., sliding the Simplicity hive back on the bottom-board would answer to graduate the entrance so as to permit workers to pass, but not queens and drones, were the edge of the bottom and the edge of the hive sufficiently accurate; in fact, I have tried the same thing, but the wood is too irregular. We either hindered the bees very much, or else the queen would find a place she could get through. I fear the edges of your hive and bottom-board would have to be of metal, to make a success.

THE X Y Z OF POTATO CULTURE.

You speak in the last GLEANINGS about the A B C of Potato Culture. Now, here in Arkansas we would rather see the X Y Z of Potato Culture. We can raise potatoes, but the trouble is to keep them. They commence rotting about as soon as they get ripe. If your book will tell us how to avoid this, so as to save them for our seed next year, I think it would be a boon to Arkansas.

Bees all lived through the winter that had honey enough, and are generally doing well. We are right in the midst of swarming time.

We have been feasting on strawberries about ten days. Next come huckleberries, and the woods are full of them.

DANIEL HOWARD.

Hot Springs, Ark., May 11, 1885.

Friend H., Mr. Terry considers the matter of keeping potatoes, very thoroughly; and I think his plan will do it, without a doubt, if you keep the temperature as low as he directs. Possibly in your climate it might be a difficult matter. It could be done, however, by means of ice, but that might be more than the potatoes are worth. By adopting the plan he suggests, however, a very little ice would keep a great many potatoes.—If strawberries and huckleberries are plentiful where you are, it seems to me it is the very place I should like to visit.

HOW MUCH CHAFF DO WE PUT OVER OUR BEES?

Just a word of explanation in regard to the amount of chaff you put over your bees in winter. In reply to Mrs. Axtell, you say, "After putting on this sheet of coarse burlap we put about a peck of loose chaff around the edges, making it impossible for the bees to push up, and so get around the ventilators in the cover." Now, is this all the chaff you put over them? My chaff cushions are from 6 to 8 inches thick, and I have thought perhaps it was too much. Have you discarded the Hill device? I use it and the burlap under my burlap cushions.

7—G. E. HILTON, 60—45.

Fremont, Mich., May 18, 1885.

Friend H., I omitted to mention the usual chaff cushions, because I supposed they were understood as a matter of course. Yes, we still continue to use the Hill device, and I think we always shall, so long as we winter as successfully as we have since using it. The Hill device makes a sort of chamber, as it were, above the brood-combs; and the cushions we use of late years are all made of coarse burlap—so coarse, in fact, that the chaff rattles through it to some extent, so you see that air has a

free passage through the loose chaff, and the cluster of bees under the Hill device have always plenty of air, no matter if the entrance is sealed up solid by an icy storm; and yet the loose chaff holds warm air enough so that the bees are never exposed to a chilling current of air.

TRIALS OF A BEGINNER IN BEE CULTURE.

I have been a silent observer and close reader of *GLEANINGS* for about a year, and have noted with much interest the various experiences of different individuals, which has tempted me to throw in my mite and make my first report, which is as follows: In August, 1883, under some peculiar circumstances I was induced to trade for 18 stands of bees—15 in box, and 3 in Langstroth hives, in various conditions as to strength; and under peculiar circumstances I was obliged to move them four miles over a very rough road one of the hottest days or nights there were in said month. The consequence was, my three best colonies, and Italians at that, in my Langstroth hives, were melted down and smothered, and several in the box hives nearly ruined. Oh what a day and night of horror! It makes my heart jump and my blood curdle when I think of what suffering of mind and body I passed through that day. Bees were dumped out on a temporary platform, honey dripping through, bees all flying, stands to fix, bee-man gone, and everybody afraid to come in the yard: house full of bees, family all fled or hid, and I alone to suffer. But before morning it turned a little cooler. I got my bee-man to come to my assistance by sending a time or two, then going after him, though he had promised to come back and set them up, but took suddenly ill after he had got his pay. But order being finally restored, the spring of 1884 found me with 14 stands.

Pine Grove, O., May 8, 1885.

S. DANIELS.

Friend D., your little story illustrates vividly the importance of commencing with one, or at the most two colonies at a time, as I have so often urged. You began by making a purchase of 18 stands, when you were unfit to manage even one. I know something about your sufferings, mental and physical, for I have been through the same troubles; whereas, had you commenced small and increased your responsibilities as you were able to bear them, you would have enjoyed the work all through.

POOR SUCCESS IN WINTERING ON SUMMER STANDS.

My bees were packed about the middle of November, as follows: I used 1½-story hives with two division-boards—one on each side of brood-nest. The frames had holes through the center, or else sticks were laid on top of the frames for passage-ways, and a cotton cushion on top of the frames. On the side of division-boards, and on top of cotton cushion, clover chaff was packed in about five inches thick, but not tight, and still I have lost heavily. I think the packing was all right, as I wintered them in the foregoing way before, and didn't lose many; but the long confinement, and poor honey which they gathered last fall, gave them the dysentery, and thus they die with plenty of honey in the hive. Unprotected bees are all dead. Out of about 450 stands of bees which were put in winter quarters last fall, only about 50 are left in this township. In our township (Eden, La Grange Co.), our assessor worked six days

before he came to me, and found only two colonies alive. He assessed our bees at \$1.00 per stand, which makes about 60 cts. tax on one hundred stands.

My apiary would make a nice picture in *GLEANINGS* now, to see the empty hives piled up along the fence, with a dozen or more hives set in rotation that are alive yet. I can not accommodate my home demand for full colonies this spring. I have borrowed neighbor S.'s apiary to raise bees and queens for sale.

HOW TO BRING CHILLED BEES TO LIFE AGAIN.

To-day noon I walked out in my apiary where I had a small nucleus standing. I opened it, and I saw they were dead (or, at least, I thought they were). I lifted out two frames where they clustered. They showed no signs of life. Then I supposed they were only chilled, because it was so cold for the last three days that the bees could not fly. So I put the frames back into the hive, and took up the hive and carried it into the house upstairs, to the stove-pipe that goes through the floor from the stove below, and took the two frames out again and blew my breath over the cluster a few times, and soon they showed signs of life. I had some syrup in the eupboard, which was made from granulated sugar and water. I went and got it, and made it milk-warm, then I took a tablespoon and dropped the syrup over and around the cluster. In less than half an hour I had my nucleus restored to life. Two hours after, I opened the hive again and the bees then came boiling up through the frames. Then I went to neighbor S.'s apiary and there I found two nuclei in the same condition, and I treated them in the same way. Then I went to neighbor E.'s, and there I found one in the same condition; again, this was treated in the same way. Now all are alive again, except one queen which was chilled too much, and died.

Now, brother bee-keepers, especially beginners, don't be in too much of a hurry to throw these supposed dead bees out of the hive, that you are sure were alive two or three days before. By the above operation you can save many a valuable queen. I have tried this before this spring, and I therefore know that you can save them.

Ligonier, Ind., May 9, 1885. J. C. MISHLER, JR.

Friend M., I do not believe that cotton is good material for the cushions, and I am inclined to think clover chaff is not porous enough. I should prefer loose oat chaff, and coarse burlap for the cushions. It seems to me it is quite important that this matter of restoring chilled bees be well understood. Hundreds of colonies might have been saved during the past cold spring, had their owners been on the alert, and looked after them as you did.

PYRACANTHA AS A HEDGE AND HONEY PLANT.

Our bees have been swarming incessantly for the last two weeks. There has not been a day but they sent out from one to four swarms, except Sunday. Mine are not "Sabbath-breakers," like friend Doo-little's. Bees are swarming on "pyracantha" hedge-plant now, which seems to be a splendid honey-plant. We have another honey-plant called McCartney rose, which the bees work on very much.

W. C. WRIGHT.

Reagan, Tex., April 21, 1885.

HOW TO PREVENT BEES FROM BUILDING BETWEEN THE UPPER AND LOWER STORIES.

Some three years ago I wrote to you, asking if there was any way to prevent bees building comb between the brood and wide frames. I did not get any satisfactory answer. I experimented, and found that strips of tin fastened to the bottom-bar of wide frames remedied the evil entirely. I should not think that tin on top-bar of brood frame, as I see by May GLEANINGS, was half as good. Just try my suggestion the coming season, and then you won't have any more inquiry in regard to preventing their building comb so that it is impossible to get the wide frames out. J. A. HAYNES.

Stockport, N. Y., May 11, 1885.

I was well aware, friend H., that bees are quite averse to attaching combs to smooth tin, and the same thing has been accomplished in a cheaper way by simply painting the top-bars. Covering all our frames with tin is pretty expensive, and even painting is somewhat so. I suppose you know that Heddon's honey-board is principally for the accomplishment of this same thing; and may it not be the cheapest way to manage it?

A GOOD MAN.

Somebody sends us a scrap from a newspaper, containing the following:

"I plows, I sows, I reaps, I mows, I cuts up wood for winter; I digs, I hoes, and taters grows; and for what I knows, I am indebted to the printer. I do suppose all knowledge flows right from the printing-press, so off I goes in these 'ere clothes and settle up—I guess."

Come to think of it, it must be that the man had been reading our new potato-book, especially if he went and settled up as he started to do.

FRIEND D. MCKENZIE PROPOSES TO SELL BEES BY THE POUND.

I have 150 colonies of bees more than I know what to do with, and so I think I could spare a few pounds, especially as they are so strong I can not catch the queens after I have got the money for them (I mean the hybrids, 50 and 25 cts. each). Wife put on the veil and helped half a day to catch 5 queens and caught only one, and that a new weak swarm, and then she said she would burn them up (but brimstone costs money), or I would not have so many bees to-day by at least 100 colonies. Don't put this in GLEANINGS.

THE INDIFFERENT IMPORTED QUEEN

You sent to replace, came to hand on the 6th inst.; three-fourths of the bees were dead (chilled, I suppose). I thought the jig was up with the whole concern. I gave them to my wife to warm up, like the chickens, while I read the mail. It was good news when she told me that the queen was alive, but smaller than lots of our bees. I call them the race-horses. What makes some bees so very large, and some so very small, when they all have "all out of doors to grow"? Why, friend Root, if I had come across the little thing in one of my hives, without knowing who she was, I would have killed her for a black virgin, and yet I suppose she will do me more good than the \$6.00 best imported. If it went by the size, "the cow could catch the hare." I had her in the hive the day before I got the postals. I thought you were like me—had more queens than postals. D. MCKENZIE.

Camp Parapet, New Orleans, La., May 8, 1885.

DO NOT BE IN TOO GREAT HASTE TO CONDEMN A QUEEN.

The imported queen you told me to winter and try further is all right this spring. Strange her eggs did not hatch last fall. Please accept thanks for your fair way of doing. CALVIN LOVETT.

Osego, Mich., April 21, 1885.

I have often known queens to refuse to lay late in the fall, although we plied their colonies with feed, and did every thing we could; yet in the spring they would be all right. In the above case the queen laid eggs, but the eggs did not hatch. As she is an imported queen, and valuable, we advised friend L. to winter her any way, and then report. We are glad to see that she has turned out all right, and we would ask friend L. to watch her carefully, and inform us if she proves as good a queen as any, after more extended trial.

DORMAN'S REPORT: A GOOD PROSPECT OF ONLY PURE ITALIANS.

As a good many are sending in their reports, I send mine. Last winter I wrote to you that I had 52 stands to go into winter quarters. They wintered well up to March; from then until the present time I have lost 22 stands, which leaves me thirty good colonies to begin the season with. They died with dysentery. Some of them had honey-dew to winter on, and I lay it to the cause of their death. Last fall they gathered nothing but honey-dew, which is something remarkable, as I have never known them to gather it before. I have four gallons of it, and it tastes like beet sugar, and is a very dark color. There has been a general cleaning-out of the black bees in this locality, which makes a splendid prospect for raising pure Italian queens.

MOVING BEES A QUARTER OF A MILE DURING WARM WEATHER.

I expect to move my bees out of town a quarter of a mile from my old location. Can I move them without their coming back? I have called the new yard Sunny Eden. W. S. DORMAN.

Mechanicsville, Ia., May 6, 1885.

Friend D., you will have quite a job if you move your bees just at this time of year so short a distance, I fear. It can be sometimes managed this way, however: Move your strongest colony first, and the returning bees will unite with the remaining stocks. Move the strongest again, and so on. When you get down to the weakest you will find them overflowing with bees. After you take the last one away, probably quite a good many bees will come back to the old locality. One of our boys tried the same experiment a couple of years ago; but so many bees came back when the last hive was moved that they made quite a respectable little swarm. They clustered and hung out over night on a bush. He then took pity on them and gave them a queen, and they built up to a good colony.—We hope Sunny Eden will be worthy of its name, friend D.

AN ITEM IN REGARD TO BEE-FEEDERS.

Take a round piece of wood, fitted loosely in the top of a can filled with honey or syrup, the edge of the lid chamfered so the bees can suck the feed up between the edge of the can and the lid. As the food is taken out, the lid will settle down till the

feed is all taken, and the lid will be at the bottom of the can. The nice part is, a bee can not drown if he should try; and another thing is, they are as cheap as dirt, and can be made any size desired.

Martinsville, Mo., Apr. 5, 1885.

D. KEECH.

I will explain to the readers, that friend K.'s feeder is made by putting a proper-sized float into any glass or tin can having straight sides, or sides nearly straight. A glass tumbler, with the sides nearly straight, I think would answer. Get a wooden wheel that just fills the tumbler while it lies at the bottom. Bevel the upper circumference of this wheel so it will make a sort of knife edge all around. Now if you fill the tumbler with honey, and drop in the wooden float, a little channel will be left all around next to the glass, with honey in the bottom of it. As fast as they lick out the honey, the float will sink. This will no doubt work nicely; but after a while your wooden float gets soaked with honey, and becomes nasty and sticky, and is apt to smell bad besides. This latter objection would, however, apply to any feeder made of wood. Feeders made of tin get rusty in time. Now, if we could have something made of glass, it seems to me it would be a pretty nice thing; but even then it would be liable to get broken.

MRS. COTTON.

The *Farm and Garden* for May has the following to say in regard to her:

Mrs. Lizzie Cotton, whose acquaintance has proved to be *very dear* to most of our beekeepers, has found means to escape the vigilance of "Fanner" Atkinson's watchdog. We see her "ads." in one or the other of the more careless agricultural papers, but as for an editorial endorsement—we had thought that a thing of impossibility.
